VOLUME 25

JANUARY TO DECEMBER, 1942

EDITORIAL AND BUSINESS OFFICES

2642 University Avenue - - - - Saint Paul, Minn

BUSINESS MANAGER

I. R. BRUCE

INDEX TO VOLUME 25

A

- Aagaard, George N.: Transfusion reactions and erythroblastosis foetalis caused by the Rh factor, 267
- Abdominal muscles, paralysis of the, Results of the Lowman operation for, 117
- Abscesses, brain, Metastatic, 108
- Accidents, automobile, The prevention of, 451
- Accumulated experience of the Department of Pathology, University of Minnesota, on neuropsychiatric material, The, 187
- Acne vulgaris, Boiled liver extract in the treatment of, 276
- Acne vulgaris, Evaluation of recent data on boiled liver extract method of treating, 796
- Adreno-genital syndrome due to adreno-cortical tumor (abstract), 223
- Advantages and limitations of certain practical adjuncts in the diagnosis of diseases of the heart, 113
- Aid, First, to the injured workman, 977
- Albuminuria, orthostatic, Nasal sinusitis and, in childhood, 458
- "Alcoholics Anonymous," Present role of, in the treatment of chronic alcoholism (case report), 204
- Anderson, David P.: The fate of the major surgical case in the small hospital, 720
- Anderson, Ernest R.: Clinical aspects of branchial fistulae, 789
- Anderson, U. Schuyler: Traumatic disorders of the peripheral vascular system, 659
- Andervont, H. B.: Recent trends in cancer research, 697
- Anemia, pernicious, Hematology of, 36
- Anesthesia in the small hospital, 723
- Associated Medical Service of Toronto, The, 616
- Auricular fibrillation, Quinidine in, 198
- Automobile accidents, The prevention of, 451
- Axillary vein, Thrombosis of the, 664

B

- Back pain, idiopathic low, Differential diagnosis of, 196
- Baker, A. B. and Noran, H. H.: The accumulated experience of the Department of Pathology, University of Minnesota, on neuropsychiatric material, 187
- Barnes, Arlie R., and Tinney, William S.: Interauricular septal defect, 637
- Barron, Moses: The use and abuse of digitalis, 990
- Basom, W. Compere, Williamson, George A., and Moe, John H.: Results of the Lowman operation for paralysis of the abdominal muscles, 117
- Beard, Archie H., and Layne, John A.: Medicolegal and sociologic aspects of diabetes mellitus, 460
- Berman, R., and Blumenthal, J. S.: Quinidine in auricular fibrillation, 198
- Blood, chilled, blood plasma and serum, The use of, 28
- Blood storage, Some aspects of, 352
- Blumenthal, J. S., and Berman, R.: Quinidine in auricular fibrillation, 198
- Blumenstein, Alex, and Eklund, C. M.: Minnesota's experience with human encephalitis caused by the equine type of virus in 1938, 103
- Boiled liver extract in the treatment of acne vulgaris, 276
- Boreen, C. A.: Boiled liver extract in the treatment of acne vulgaris, 276

- Borg, Joseph F.: Prognosis in heart disease: contributions of the electrocardiogram, 709
- Brain abscesses, Metastatic, 108
- Branchial fistulae, Clinical aspects of, 789
- Bristol, Leverett D.: Health and safety of wartime workers, 441
- Broadie, Thomas E.: Maintenance of adequate personnel for hospitals, 549
- Brown, Alex E.: The use and abuse of the sulfonamides, 859

Book Reviews

- American Medical Association: Food charts; foods as sources of the dietary essentials, 1020
- American Pharmaceutical Association: National formulary, 516
- Anderson, Gaylord W., and Arnstein, Margaret G.: Communicable disease control, 157
- Andes, Jerome E., and Eaton, A. G.: Synopsis of applied pathological chemistry, 157
- Blair, Vilray P., and Byars, Louis T.: Cancer of the face and mouth, 318
- Boas, Ernst P.: Treatment of the patient past fifty, 676

Facing the Future

This new year may prove very trying for many of us. The demands on industry and labor for more and more production are increasing. The strain and tension of the times are bound to be reflected in the faces of people from coast to coast. America must face the future at its best. Realizing this, we feel that we can be of service by helping America look its best in 1942.

Luzier's Fine Cosmetics and Perfumes are made in a wide range of shades and types from which a selection can be made to meet individual requirements. The Luzier formula is available to the medical profession and, in specific cases, raw materials may be obtained for patch testing. Preparations by Luzier are distributed by Cosmetic Consultants who assist with the selection of suitable cosmetics and explain how they are best applied to achieve the loveliest cosmetic effect.

**DON'T JUDGE THE WORTH
OF THIS *Portable*
X-RAY UNIT BY ITS SIZE**

BECAUSE the G-E Model F-3 Office-Portable X-Ray Unit seems so small in size, and its price is moderate, don't overlook its practical diagnostic range and its ability to produce radiographs of high quality.

The G-E Model F-3 is a unit that you can rely upon for satisfactory, dependable x-ray performance within its range—in your office or at the patient's bedside—wherever adequate roentgenological service is not otherwise available.

Think what a valuable assistant the F-3 could be. Then, why not do as hundreds of value-wise medical men did? Judge the F-3 strictly on performance. See this fine unit right in your own office. Then you can actually use and handle the F-3 just as you would in your daily practice. And you'll get first-hand information about its refined, simplified control and its unusual flexibility.

Here's all you have to do to arrange for this interesting demonstration: Just clip, sign, and mail the convenient coupon, today. We'll do the rest.

---CLIP, SIGN, and MAIL, TODAY---

I'm interested in an actual working demonstration of the G-E Model F-3 Office-Portable X-Ray Unit. When next in this vicinity, please have your representative arrange with me for a time most convenient to me.

THE SLOWER-BURNING CIGARETTE MEANS LESS NICOTINE IN THE SMOKE!

MOST physicians concede that the leading constituent of cigarette smoke from a physiologic standpoint is *nicotine*.

Medical—research authorities* find that the slower-burning cigarette produces less nicotine in the smoke. Camel's scientific tests** show that Camels burn slower and that the smoke of Camels contains less nicotine than the average of the other brands tested.

When suggesting a program to improve a patient's smoking hygiene, you may find it of value to recommend Camel, the slower-burning cigarette.

Camel offers a double advantage: Besides the reduction of nicotine intake (and all that this implies in the lessening of physiologic irritation), Camel gives more assurance of your patients' cooperation. Camel's slower-burning, costlier tobaccos maintain *the essential "pleasure factor" in smoking*.

**J.A.M.A.*, 93:1110, October 12, 1929

Bruckner, Die Biochemie des Tabaks, 1936

***The Military Surgeon*, Vol. 89, No. 1, p. 7, July, 1941

A RECENT ARTICLE by a well-known physician in a national medical journal presents new and important information on the subject of cigarette smoke and the burning rate of cigarettes. A comprehensive bibliography is included. Let us send you a reprint of this article for your own inspection. Write to Camel Cigarettes, Medical Relations Division, 1 Pershing Square, New York City.

CAMEL

THE CIGARETTE OF COSTLIER TOBACCOS

*Tons of Liver reduced to
thimble-fuls of concentrate for the —*

PERNICIOUS ANEMIA PATIENT

THE STORY OF LIVER and pernicious anemia seems old today, yet less than 15 years have passed since the original announcement of MINOT and MURPHY.

During this period the search for more effective liver therapy has been pursued by many workers. Isolation of the active principle of liver has been their goal.

In 1929 COHN succeeded in preparing the first experimental injectable liver extract. In 1931 Lederle made a significant contribution with the first Council-accepted, commercially available liver extract for intramuscular use. Liver therapy was thus revolutionized! Subsequently, extracts of greater and greater concentration have resulted from Lederle's constant quest for a better understanding of the antianemic substance.

Tons of liver are used daily in the production of Lederle's "1 cc. CONCENTRATED SOLUTION LIVER EXTRACT" and other liver preparations. A veritable blessing for the pernicious anemia patient who benefits by the high potency, convenience, and great saving afforded by these contributions to medicine.

LEDERLE LABORATORIES, INC.
30 ROCKEFELLER PLAZA NEW YORK, N. Y.

No Lack in Biolac!

WITH THE sole exception of vitamin C, Biolac provides completely for the formula needs of normal infants throughout the entire bottle period. From the time when infants consume a full quart of formula per day, here's how certain essential food factors supplied by Biolac feedings compare with the minimal nutritional requirements recognized by the U. S. Food and Drug Administration.

	MINIMAL REQUIREMENTS	BIO-LAC FEEDINGS
PROTEIN (gms./lb. body weight) . . .	1.4 to 1.8* . . .	2.2†
CALCIUM (gms./day)	1.0* . . .	1.0
IRON (mgms./100 calories)	0.75 . . .	1.25
VITAMIN A (U.S.P. Units/day)	1500. . . .	2500.
VITAMIN B ₁ (U.S.P. Units/day)	83. . . .	85.
VITAMIN B ₂ (mgms./day)	0.5 . . .	2.
VITAMIN D (U.S.P. Units/100 calories) .	50. . . .	63.

*The Food & Drug Administration has not promulgated minimum requirements for protein and calcium in infancy. The values shown are those recommended by the National Nutrition Conference.

†When Biolac formulas are fed in the amount of 2½ fl. oz./lb. body weight.

Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrate of vitamins A and D from cod liver oil, and ferric citrate. Evaporated, homogenized, *sterilized*.

Borden's BIOLAC

A BORDEN PRESCRIPTION PRODUCT

Storm Center

...THE BRAIN

When electroencephalography records the brain potential of epileptic patients prior to and after the use of Kapseals Dilantin Sodium, the oscillograph usually depicts more normal brain waves. Furthermore, seizures diminish in frequency and severity. As a result of this, the patient's general attitude and behavior are favorably influenced and he is permitted to enjoy a more normal life.

A combined report of thirteen clinicians states that in 404 out of 595 epileptic patients, Dilantin Sodium was more effective than other anti-convulsants¹. Its value in patients not responding to other medication has been reported². All in all, Dilantin Sodium (phenytoin sodium), a product of long and systematic research in clinic and laboratory, marks a definite forward step in the management of epilepsy. Complete details upon request.

"IN THE HOLLOW OF YOUR HAND"

The NASALATOR

New, convenient vest-pocket applicator for

NEO-SYNEPHRIN HYDROCHLORIDE SOLUTIONS

(*laevo-alpha-hydroxy-beta-methyl-amino-3
hydroxy ethylbenzene hydrochloride*)

SOLUTION

A SIMPLE little device, now accepted by the Council on Physical Therapy, which fits into the purse or vest-pocket and holds a good supply of the vasoconstrictor, Neo-Synephrin Hydrochloride.

The Nasalator is constructed of transparent plastic material, and is easily refilled by means of a dropper.

A quick inhalation in each nostril brings symptomatic relief of the nasal congestion accompanying colds, rhinitis and sinusitis.

EMULSION

Neo-Synephrin Hydrochloride Solution

Forms to be used with the Nasalator

$\frac{1}{4}\%$ in Saline Solution ($\frac{1}{2}$ -oz. and 1-oz. bottles)

$\frac{1}{4}\%$ in Ringer's Solution with Aromatics
($\frac{1}{2}$ -oz. and 1-oz. bottles)

1% in Saline Solution ($\frac{1}{2}$ -oz. and 1-oz. bottles)

Other Neo-Synephrin Hydrochloride Dosage Forms

Emulsion— $\frac{1}{4}\%$ ($\frac{1}{2}$ -oz. and 1-oz. bottles with dropper)

Jelly— $\frac{1}{2}\%$ (in collapsible tubes with nasal applicator)

JELLY

For Acute Hypotension in Surgical Conditions

1% Sterile Solution of Neo-Synephrin Hydrochloride.

1 cc. ampoules, boxes of 6 and 60; 5 cc. rubber-capped vials.

Advantages of NEO-SYNEPHRIN HYDROCHLORIDE

Promptly shrinks engorged mucous membranes. Provides prolonged relief. Less toxic in therapeutic dosage than ephedrine. Effective on repeated application. Does not "sting."

Medicine's *Newest* Equipment **DESIGNED FOR UTILITY . . EFFICIENCY . . DURABILITY**

Here are the newest contributions to medical office efficiency—Ritter Ear, Nose and Throat Units—Chairs—Stools—brought together into one compact unit . . . bringing about new operating ease . . . efficiency and patient attractiveness.

All operating essentials are at your finger tips—with water, air, electricity, waste and vacuum within easy arm's reach.

Above is a typical Ritter installation.

Ritter
EQUIPMENT

*Built Up to a Standard-
 Not Down to a Price*

We will gladly demonstrate this equipment . . . now on our display floors . . . or will send literature. No obligation, of course.

Brown & Day, Inc.

62-64 East 5th St.

St. Paul, Minn.

In the past a frequent complaint from mothers was the expense incurred when the large bottle of antiricketic was accidentally upset.

OLEUM PERCOMORPHUM

Even if the bottle of Oleum Percomorphum is accidentally tipped over, there is no loss of precious oil nor damage to clothing and furnishings. The unique Mead's Vacap-Dropper* is a tight seal which remains attached to the bottle, even while the antiricketic is being measured out. Mead's Vacap-Dropper offers these extra advantages also, at no increase in price:

Unbreakable

Mead's Vacap-Dropper will not break even when bottle is tipped over or dropped. No glass dropper to become rough or serrated.

No "messiness"

Mead's Vacap-Dropper protects against dust and rancidity. (Rancidity reduces vitamin potency.) Surface of oil need never be exposed to light and dust. This dropper cannot roll about and collect bacteria.

Accurate

This unique device, after the patient becomes accustomed to using it, delivers drops of uniform size.

No deterioration

Made of bakelite, Mead's Vacap-Dropper is impervious to oil. No chance of oil rising into rubber bulb, as with ordinary droppers, and deteriorating both oil and rubber. No glass or bulb to become separated while in use.

How to Use MEAD'S Vacap-Dropper

Remove both top and side caps. Wipe dropper tip. Place forefinger firmly over top opening and regulate rate of flow by varying the degree of pressure. Oleum Percomorphum is best measured into the child's tomato juice. This is just as convenient and much safer than dropping the oil directly into the baby's mouth, a practice which may provoke a coughing spasm.

*Supplied only on the 50 c.c. size; the 10 c.c. size is still supplied with the ordinary type of dropper.

OLEUM PERCOMORPHUM

More Economical Now Than Ever

MEAD JOHNSON & COMPANY • EVANSVILLE, INDIANA, U. S. A.

Please enclose professional card when requesting samples of Mead Johnson products to cooperate in preventing their reaching unauthorized persons.

An Effective Medicinal Weapon Against Depressions

Mild pathological depressions may accompany a variety of clinical syndromes. In addition to prescribing whatever forms of therapy are indicated for the individual condition, it may also be advisable to treat the underlying or concomitant depression.

If, in the judgment of the physician, treatment of this depression appears advisable, the administration of Benzedrine Sulfate Tablets will often prove useful. In depressive psychopathic cases the patient should be institutionalized.

Benzedrine Sulfate Tablets offer "a therapeutic rationale which, in its very efficiency, cuts across the old categories". (Parker, M. M.—J. Abnorm. & Soc. Psych., 34:465, 1939)

Initial dosage should be small, 2.5 to 5 mg. If there is no effect this should be increased progressively. "Normal Dosage" is from 5 to 20 mg. daily, administered in one or two doses before noon.

Benzedrine Sulfate Tablets are now manufactured in two sizes. In writing prescriptions please be sure to specify the tablet-size desired, either 5 mg. or 10 mg.

Benzedrine Sulfate Tablets

Brand of amphetamine sulfate

Vitamins were there all the time!

Vitamins have performed their vital functions for untold ages—but modern science has accomplished something new. It has revealed specific functions of vitamins, isolated many of them, and taught us how to make some of them synthetically. As a result, we can now make from the pure vitamins pharmaceutical prepa-

rations of great potency appropriate for the treatment of each of the various clinical syndromes caused by lack of one or more of these essential food factors.

Fifty-five years of experience in making fine pharmaceuticals equip The Upjohn Company to prepare these vitamin products for you.

NICOTINIC ACID
(UPJOHN)

ASCORBIC ACID
(UPJOHN)

THIAMINE HYDROCHLORIDE
(UPJOHN)

Intimate knowledge of the properties of those vitamins that have been isolated has made possible their determination by physical and chemical measurements, as well as by biological assay.

Upjohn

KALAMAZOO, MICHIGAN

Fine Pharmaceuticals Since 1886

IPRAL A safe, effective sedative usually inducing 6 to 8 hours sleep closely resembling the normal from which the patient awakens generally calm and refreshed. Over 15 years of use has shown it to be markedly free from untoward effects in the usual therapeutic dosage.

HOW SUPPLIED

IPRAL CALCIUM (calcium ethylisopropylbarbiturate). 2-grain tablets and powder form for use as a sedative and hypnotic. $\frac{3}{4}$ -grain tablets for mild sedative effect throughout the day.

IPRAL SODIUM (sodium ethylisopropylbarbiturate). 4-grain tablets for pre-anesthetic medication.

Q. I find canned fruits very convenient, but are they as good for my family as the kind prepared at home?

A. Certainly. The principal dietary values of fruits are carbohydrates, vitamins, and minerals. The canning process does not affect the carbohydrates or mineral values of fruits. Also, canning has little or no effect on the vitamins in this type of food. Even vitamin C, the most easily destroyed of the vitamins, is well retained in canned fruits, because of the high degree of protection from oxygen during the canning process. ⁽¹⁾

THE PRESENT STATUS OF HORMONE THERAPY

MAX HOFFMAN, M.D.

Saint Paul, Minnesota

THE advances in the field of endocrinology in the last decade have been so rapid that even the physician who is especially interested in this subject has difficulty in keeping abreast of the new developments.

The busy practitioner of medicine has a troublesome task in securing the facts regarding endocrine diseases and hormone therapy. Often his only sources of information are the pamphlets and booklets sent out by the manufacturers of chemical hormone products.

Some of the concerns producing hormones have done a great deal to further progress in this field through their own research work and in supplying materials for experimental and clinical observations to other workers. To these firms we can only be grateful. Others, however, either directly or indirectly misrepresent the value of hormone therapy and their own products.

It would be difficult to estimate the amount of money wasted in buying impotent hormone products and in the use of hormone therapy where it is not indicated. The sum must be tremendous.

If we should exclude from the list of endocrine entities, the thyroid diseases, diabetes mellitus, and menopause in women, the incidence of diagnosable endocrine disturbances would not be common. Also within the group in which we are able to make a diagnosis of endocrine disease there are many conditions which cannot be treated by hormone therapy.

The promiscuous use of endocrine substances in conditions where there is no accurate indication for such therapy is not only wasteful but

in some cases is actually harmful and serves only to bring discredit on this form of therapy.

The diagnosis of endocrine states is usually not easy and often the physician is tempted to try some form of hormone treatment without having any good idea as to just what gland is involved. Fortunately, he usually chooses some member of the group of gonadotropics and with the doses commonly used he is not apt to do much damage.

The unsatisfactory state of a good deal of endocrine therapy is due to the fact that we often do not know the exact rôle played by a hormone in the body or the requirements of the body for this particular hormone.

It would be impossible to go into a detailed discussion of the individual hormones at this time; therefore an attempt will be made to evaluate, in the light of our present knowledge, the hormone preparations now available to the physician for clinical work.

Pituitary Gland Hormones

The pituitary gland has been called the master or motor gland and through its various hormones controls the activity of the other endocrine glands in the body. The clinical value of the hormones of the posterior lobe has so well been established that a discussion at this time will not be necessary.

Although the anterior lobe is said to produce seven or more hormones, only two types are available at this time. They are the "growth hormone," and the "gonadotropic" or sex stimulating hormone.

Our knowledge of the growth hormone is still very much in the experimental stage and the literature does not contain many reports

Read before the annual meeting of the Minnesota State Medical Association, St. Paul, Minnesota, May 28, 1941.

regarding its effectiveness. Several series of clinical investigations show that it has some value in stimulating growth in instances where growth has been retarded. The results as a whole have not been spectacular, but indicate that this form of therapy is not without value. To achieve the best results it should be started early in life and the treatment must be kept up intermittently for periods as long as two years.

The gonadotropic hormones have been the subject of considerable discussion for the last two years. They have received considerable abuse, some of which is unjustified. The poor results secured following the use of these hormones have been at least in part due to the improper selection of cases, and the use of impotent hormones, or too small amounts of the hormone.

Although the claims for the value of this hormone made by some of the manufacturers are highly exaggerated, these preparations are of value in many instances, but not in all the conditions which are indicated in the pamphlet accompanying the box.

There are three main types of this hormone:

1. Anterior pituitary gonadotropic: This is secured from the gland itself or from the urine of castrates or menopausal urine.
2. Pregnancy urine gonadotropic (A.-P.-L. or chorionic gonadotropin).
3. Pregnant mares' serum (equinin).

These three gonadotropins vary somewhat in their action. The anterior pituitary hormone is capable of stimulating the ovary in the absence of the pituitary gland whereas the chorionic gonadotropin from pregnancy urine has very little effect on the ovary if the pituitary is intact, and none if it has been destroyed. The hormone from the pregnant mares' serum has more the action of the pituitary hormone than does the pregnancy urine hormone.

The information that we have today indicates that the chorionic gonadotropins are of very little value if we want to stimulate the ovary. There is some evidence that very large doses might be of value in gynecological conditions. More promising but still rather ineffective in gynecologic situations is the use of anterior pituitary hormones. Pregnant mares' serum runs a

second best. The whole subject of ovarian stimulative therapy is in a very confused state with most of the evidence showing that this form of therapy is not very effective. At best the physician shouldn't expect too much from any of these hormones in ovarian insufficiency.

More promising, but still not very spectacular in results except in occasional instances, is the effect of these hormones in stimulating maturation in the male. The early enthusiasm for this type of treatment in cryptorchidism has somewhat abated. The success of this form of therapy in numerous reports varies from 20 to 80 per cent. The lower figure is probably the more accurate. For those who believe that the gland should be brought into the scrotum at an early age, this form of therapy can be tried before surgery is resorted to. It is a well known fact that in many cases of cryptorchidism there is only a delay in the descent of the testis which will naturally correct itself in time.

Experimentally all the gonadotropins will maintain spermatogenesis after the pituitary gland has been ablated, if given early. Clinically these hormones are of very little, if any, value in oligospermia or aspermia.

The manufacturers of pregnant mares' serum claim that this hormone will produce ovulation. These claims are based on early work by two investigators whose results have not been verified by subsequent researches. The other claims made for this hormone have not been substantiated, and, inasmuch as it is an expensive preparation, its use at present should not be encouraged.

Parathyroid Hormones

The outstanding disturbance in parathyroid deficiency is a lowering of serum calcium which results in tetany and a train of other symptoms. Therapy is directed toward raising the calcium level in the blood. In milder cases, calcium administered together with viosterol is all that is necessary. In the more severe cases the natural hormone extracted from the gland, or the synthetic hormone, dihydrotachysterol, is very effective.

Because of its ease in administration, dihydrotachysterol is now generally preferred over the natural hormone. It can be given orally and 5 to 10 c.c. will cause a satisfactory rise in blood calcium in three to nine days. Often 2

to 6 c.c. a week will maintain a normal calcium blood level.

One must use this hormone with care as an excessive dosage will raise the blood calcium sufficiently to cause the formation of calculi in the kidneys and produce calcinosis in other organs.

Adrenal Cortical Hormone

The hormone of the medullary portion of the adrenal gland is epinephrine and its use is so well known that a discussion is not necessary.

No single hormone of the adrenal cortex either extracted from the gland or synthetically produced is capable of replacing all the functions of this organ. Some are capable of correcting the disturbances in the electrolytes, but have little effect on the carbohydrate metabolism. Other preparations have more action on the carbohydrate function and less on the sodium and potassium metabolism. Some of the preparations on the market have very little action of any kind. There is a great deal of variability in the potency of the products produced by different manufacturers, and one should select a preparation approved by the Council of Pharmacy of the American Medical Association.

The natural adrenal cortical hormones are very expensive and their uses should be restricted to definite cases of Addison's disease. Often in milder cases a restriction of potassium, and an increase of sodium in the diet may give a satisfactory result without hormones. By using this type of diet the amount of hormone necessary can frequently be reduced. In some cases of adrenal cortical insufficiency the hormone is necessary only during infections, or before or after operation.

The only synthetic adrenal cortical hormone now on the market is desoxycorticosterone, and is supplied by various manufacturers under different names. This product is constant in its potency and is very effective in restoring the sodium-potassium balance, but it has little action on the carbohydrate disturbance. It is capable experimentally of keeping adrenalectomized animals alive for long periods, and is often very valuable in the treatment of Addison's disease. However, it differs from the natural hormone in that overdosage may be very serious and a number of deaths have been reported following its use. In order to control the proper dosage, ex-

tensive laboratory control is necessary. For the general practitioner this preparation is not recommended. Although the natural extracts are more expensive, overdosage is not harmful.

The Ovarian Hormones

The physician has developed an intense interest in the ovarian hormones because the frequency of ovarian disturbances is much greater than most of the other endocrine conditions met with in clinical medicine.

There are two types of these hormones: the estrogenic or endometrial proliferative hormone and the luteal or secretory hormone. These hormones, together with the gonadotropic hormone of the anterior pituitary gland control the menstrual cycle. The exact mechanism that occurs in menstruation is not known. For that reason, even though we have potent ovarian hormones, treatment with these hormones in menstrual disturbances has not been very satisfactory.

The estrogenic hormones have a definite action in stimulating the development of the accessory sex characters in the female. These changes are usually very temporary and have a tendency to disappear when the hormone is withdrawn.

There are only two definite indications for the use of estrogens in therapy. These are gonorrheal vaginitis in children and in the treatment of the menopause in females.

Treatment can be administered by injection, by inunction and by the oral route. The choice of treatment would be determined by the expense or by the need for a quick response.

The other ovarian hormone is progestin or progesterone, and it is the hormone produced by the corpus luteum. The effect of this hormone on the endometrium after the estrogenic hormone has caused the proliferative changes completes the menstrual changes.

It has been used for dysmenorrhea and the functional types of bleeding that occur in the menses and in the menopause. Any beneficial action in these cases is very doubtful inasmuch as we know very little about the cause or causes of functional uterine bleeding.

The only reasonable indication for the use of this hormone is in cases of threatened or periodic abortion. In the first instance the therapy must be carried out over long periods and its use is expensive. Either the injectable or the oral forms of therapy can be tried.

The Testicular Hormone

The male hormone is available in several forms, as testosterone propionate for injections or for cutaneous application or as methyl testosterone in tablets for oral use. It is a potent hormone and is capable of stimulating the development of the male secondary sex apparatus. Its effect is temporary and disappears when the hormone is discontinued. It is particularly valuable in cases of castration in young males. It also is of great value in adults who have lost their testicular function and who suffer from this loss. Not all castrates have disabilities resulting from the loss of this hormone.

The use of this hormone in children is rarely justifiable unless the testes have been destroyed by accident or disease. There is a definite danger that it can produce an atrophy of the testis when it is administered to an individual with functioning gonads.

There is no good evidence that this hormone is of real value in the treatment of gynecological disturbances. Several instances have been reported where masculine changes have been stimulated to develop in women who have received this hormone.

It is not effective in stimulating spermatoge-

nesis; in fact most of the evidence shows that it inhibits sperm formation and development.

All forms of testosterone are potent, but most of the other products that are said to contain the male hormone have so little activity that they are useless. Testosterone, like many of the other hormones, is expensive, especially when one uses the dosages that are necessary to achieve a good result.

Conclusions

1. Aside from a few well-known diseases, the number of endocrine disturbances is not great.

2. All individuals who have endocrine diseases do not require hormone therapy.

3. Although most of the hormones produced and marketed by established firms are potent preparations, many on the market are not.

4. Hormone therapy is, for the most part, substitutive therapy, and inasmuch as it is usually a very expensive form of treatment for the patient, it should be administered only when there is a clear-cut indication for its use.

5. The physician should attempt to secure his information regarding hormone therapy from articles in reputable medical journals, written by capable men.

TEN CASES OF PARALYSIS AGITANS TREATED WITH VITAMIN B₆

CHARLOTTE L. MELLER, M.D.

Minneapolis, Minnesota

THE reports in the literature on the treatment of paralysis agitans with vitamin B₆ have in some cases been encouraging^{1,2} and in others discouraging.³ Our material consists of four cases of postencephalitic and six cases of idiopathic paralysis agitans.

As our patients are all relief clients whose diets could easily have been deficient in all vitamins, they were given brewer's yeast, 10 grains three times a day, and cod-liver oil tablets, one, three times a day. From previous experience we have found that these doses have no specific therapeutic effect in this illness. Fifty mgm. of vitamin B₆ were given daily, subcutaneously or intravenously, for ten days, then increased to 100 mgm. for three or four doses. The dose was then either continued or decreased, depending upon the patient's response. Patients responded

promptly to vitamin B₆ and quickly reached a degree of improvement beyond which even larger doses brought no benefit. After this degree of improvement was attained, the patient was maintained on 50 mgm. subcutaneously on alternate days. The intravenous route of administration seemed to offer no advantage over the subcutaneous. Not all patients were able to follow this routine identically because of practical considerations. However, attempt was made to keep treatment as uniform as possible.

All our patients had been taking drugs of the atropine series for many years and considerable difficulty was encountered when these medications were suddenly discontinued. In Case No. 6 a mild panic reaction occurred upon sudden discontinuation of hyoscine and stramonium. Therefore, these medications were gradually discon-

PARALYSIS AGITANS—MELLER

TABLE I. SUMMARY OF CASES OF PARALYSIS AGITANS

Case	Age	Duration of Illness	Type	Severity of Disease	Disability	Dosage	Duration of Treatment	Results of Treatment
1	30	18 Yrs.	Post-E	Severe	Practically bedridden	50 mgm. for 20 days; 100 mgm. for 10 days all intravenously	1 mo.	None
2	58	4 Yrs.	Idio	Moderate	Up and around but not able to work; speech indistinct	50 mgm. subcutaneously every other day	5 mo.	Gained weight, movements easier, walks steadier, spasticity less, tremor unchanged
3	53	10 Yrs.	Idio	Severe	Practically bedridden; body aches and pains	50 mgm. daily for 18 days; 100 mgm. daily for one week; then 50 mgm. twice weekly—all intravenously	5 mo.	Said "movements easier, walks faster, feels better." Spasticity appeared unchanged; tremor unchanged
4	32	2 Yrs.	Post-E	Mild	Up and around; had to quit work	50 mgm. daily for 1 week; 100 mgm. on alternate days for 14 doses; 50 mgm. twice a week since—all intravenously	5 mo.	Insisted he felt better. Objectively no change noted
5	69	11 Yrs.	Idio	Severe	Up and around	50 mgm. daily subcutaneously for 10 days; alternate days since	5 mo.	Gained weight, movements easier, walks steadier, spasticity less; tremor unchanged
6	56	20 Yrs.	Idio	Severe	Up in chair; seldom walked	50 mgm. subcutaneously daily for 20 doses; then alternate days	5 mo.	Gained weight, movements easier, walks erect and steadier, tremor much less, spasticity much less
7	53	5 Yrs.	Idio	Moderate	Up and around; did housework very slowly; marked masklike face	50 mgm. intravenously daily	19 days	Markedly improved; masklike face disappeared
8	36	14 Yrs.	Post-E	Mild; has frequent oculogyric crises	Up and around but not able to work	50 mgm. daily for week; 100 mgm. alternate days for 12 doses. 50 mgm. twice weekly	4 mo.	Said "movements easier, walks faster, feels much better." Spasticity appeared unchanged, tremor unchanged
9	57	11 Yrs.	Idio	Moderate	Up and around; tremor marked; shuffling gait	50 mgm. subcutaneously every other day	3 mo.	Gained weight, movements easier, walks steadier, spasticity less, tremor unchanged
10	57	10 Yrs.	Post-E	Mild	Up and around but not able to work	50 mgm. subcutaneously daily 12 days—then every other day	2 mo.	Insists that he feels better and can walk faster. Objectively no change noted

tinued until the patients felt secure without them.

As a partial control, three patients were treated with normal saline. One of these reported that he thought that he felt better. None of them showed any objective change.

Our work is summarized in the accompanying table.

None of the patients improved sufficiently to resume previous activities. However, sufficient

improvement was obtained to warrant the use of this drug in the treatment of paralysis agitans. Case 6 most nearly approached the improvement reported by Jolliffe. This patient's improvement was rather startling. Chair-ridden and helpless for two years, he is now able to walk almost erect. Though his tremor is still present to a marked degree, he is now able to feed himself.

Of the ten patients, only one (Case 1) failed

to respond in some measure. The others reported improvement out of proportion to the objective findings demonstrated. The improvement consisted of a feeling of relaxation, decrease of spasticity, disappearance of pain and increased feeling of well-being. It was common for them to report that following the injection they were able to take a "restful nap." Although no objective change in tremor was noticeable, the patients reported that they had better control of their muscles (arms and legs moved with more assurance, and the tremor was not so annoying).

Cases 1, 4, 8 and 10 are postencephalitic. These showed no objective improvement though cases 4, 8 and 10 made enthusiastic reports about their improvement. Cases 2, 5, 6, 7 and 9 made definite objective improvement as evidenced by improved posture, decreased rigidity, more elastic gait and rapid locomotion. They enjoyed walking to the clinic where previously it had been necessary for them to take the streetcar. More expression appeared in their faces. The general condition of these patients improved as shown by substantial weight gains. The patient in Case 3 was bedridden, her response, which was slight, was nevertheless definite. Her penmanship became legible. She was able to lift herself to a sitting position. She never progressed beyond this point.

Comments

We are in agreement with Jolliffe, Baker and Zelig that the postencephalitic paralysis agitans cases do not respond to B₆ therapy.

At the beginning of this study, the medicine was given intravenously. Several times the comment was made that the improvement was due to the fact that the examiner was giving personal attention to these patients which they had not previously received. Therefore, in an attempt to eliminate the influence of suggestion, vitamin B₆ was given subcutaneously by the nursing staff, which personnel changed periodically. No untoward reaction followed any injection.

Summary

It is our opinion that vitamin B₆ in the treatment of idiopathic paralysis agitans decreases pain and rigidity and increases general well-being. Whether this is due to specific action of vitamin B₆ in paralysis agitans or to a coincidental vitamin B₆ deficiency is not known. Though this improvement may not be a great achievement, it is very worth while in a disease of this chronicity. Inasmuch as response is very rapid, a short therapeutic trial of vitamin B₆ is justified in any case of idiopathic paralysis agitans.

Cases taken from the Neuropsychiatric Service of Minneapolis General Hospital, J. C. Michael, M.D., Chief of Staff. Vitamin B₆ (Hexabione) Pyridoxine Hydrochloride furnished by Merck & Co., Inc., Rahway, New Jersey.

PRESENT-DAY TREATMENT OF PNEUMONIA

HARRY G. WOOD, M.D.

Rochester, Minnesota

OLDER physicians, I am sure, remember the type of pneumonia with which we had to deal before the first world war. It was pneumococcic in origin and lobar in type. In general, its behavior was eminently respectable. By this, I mean that the mortality incidence was low and complications, such as empyema, were infrequent.

Recovery followed crisis and this generally occurred in the seventh to ninth day of illness.

In 1918 and 1919, the last influenza pandemic occurred. With this, there were many respiratory complications and the so-called influenza pneumonia was prevalent. This was a nonpneumococcic and bronchial pneumonia. In the decade following the war, the pneumococcus could rarely be found. In some instances *Hemophilus influenzae* (Pfeiffer's bacillus) did appear to be the

From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Read before the Annual Meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 29, 1941.

infecting organism. More frequently, some type of streptococci was demonstrated.

During the war of 1914 to 1918, high concentrations of oxygen first came into general therapeutic use. Oxygen therapy was really the first important advance made in the modern treatment of pneumonia. It still remains the best sheet anchor in many instances. Every patient who is cyanotic or has other evidence of anoxemia should receive oxygen in addition to the other treatment employed. The first effective use of oxygen was by the nasal catheter. Later, expensive oxygen chambers were built by many hospitals. At present the oxygen mask or tent has supplanted these. Although many patients tolerate the mask or nasal tube well, the tent, when available, is the preferable method of administration.

Oxygen is equally, or even more, valuable in treatment of acute pulmonary edema. For this condition, a 100 per cent concentration under increased pressure is used. In many instances this procedure carried out for twenty to thirty minutes will cause much improvement. In cases in which satisfactory improvement does not occur, aspiration through the bronchoscope must be considered. This procedure frequently completely frees a lung of all evidence of edema when oxygen treatment has not proved satisfactory.

During the past decade, pneumococci again have been demonstrated with increasing frequency as the causative organism in cases of pneumonia. With increasing frequency also, the lobar type of consolidation again has been seen. In this connection, however, I wish to mention the non-pneumococcic, so-called virus type of pneumonia which seems to be becoming more prevalent. I shall refer to this type again.

Also in recent years, instead of four groups of pneumococci, some thirty-one strains have been isolated and for all of them typing serums are available. For more than half of them, satisfactory antisera have been developed. Owing to the more recent development of extremely valuable chemotherapeutic agents, we are likely to forget the extreme importance of serum therapy in the treatment of pneumonia. Nevertheless, pneumococcic antisera must be considered the second great advance made in the modern treatment of pneumonia. Although the high cost, together with the brilliant results obtained with chemotherapeutic agents, has largely curtailed the use of antiserum, it remains an agent of much value. Its use in combination with chemotherapy

must be considered in all cases of pneumonia in which there is a severe infection of the blood stream. It continues to be so used routinely in Baltimore and some other cities in which the serum is supplied by the municipality without cost to the patient.

With these introductory remarks, I come to the most recent and, unquestionably, the greatest advance that has been made in the treatment of pneumonia. I refer, of course, to chemotherapy.

Chemotherapy

Sulfanilamide first became available to the profession as a whole for the treatment of pneumonia in 1936. I am sure all physicians have had cases in which the effects of its administration seemed miraculous. As a result, it is expected that the clinical manifestations of patients will be greatly modified and completely controlled almost in a matter of hours. However, it was found that toxic manifestations were frequent and that many patients were intolerant to the drug, no matter whether given by mouth or intravenously. The most common manifestations were anorexia, severe headache, protracted nausea and vomiting. Psychotic manifestations also occurred. The complications caused by toxicity will be considered in greater detail when discussing sulfapyridine.

These features led to continued search for therapeutic agents which had even greater physiologic effect and fewer toxic manifestations. Although a number of preparations have had some trial clinically, sulfapyridine and sulfathiazole have recently been used almost exclusively. Both have other and valuable functions, but I will consider them only in so far as they are used in the treatment of pneumonia.

Sulfapyridine is definitely more efficacious in the treatment of pneumonia than sulfanilamide, but toxic manifestations are about as frequent with the former as with the latter, and nausea and vomiting are even more common. Sulfathiazole is much less toxic and is of value in the treatment of pneumonia, but its physiologic effect is considerably less than that of sulfapyridine. Both drugs are eliminated rapidly, and when given orally the interval between doses must not be more than four hours. When the soluble sodium salt of either drug is used intravenously, the interval between doses should not be greater than eight hours. If oral administration is possible, the concentration in the blood of the free

drug can be better maintained by oral doses between intravenous doses. Satisfactory concentrations for both drugs are generally between 3 and 6 mg. per 100 c.c. of blood. Occasionally, a concentration of 10 mg. per 100 c.c. of blood seems more effective.

In administering either drug, in most instances an initial dose of 2 gm. followed by 1 gm. at intervals of four hours seems sufficient. When the sodium salt has been used intravenously, it has been my practice to give 50 c.c. of a 5 per cent solution at intervals of eight hours.

The toxic manifestations following the administration of sulfapyridine are similar to those following the use of sulfanilamide. Nausea and vomiting are frequent; central nervous system disturbances such as vertigo and headache are common; and in about 4 per cent of cases sufficient mental disturbance occurs to be classified as psychosis. In this connection, I wish to state that Dr. Bullowa, with whom I have recently had the opportunity of discussing this subject, informed me that many of the patients with pneumonia who entered the hospitals in New York were alcoholics. In his opinion, the psychosis was the result of malnutrition and avitaminosis; in many cases the mental symptoms cleared rapidly after the administration of thiamine chloride and nicotinic acid.

Cyanosis is generally present in some degree but rarely necessitates withdrawal of the drug. Rashes and drug fever are not uncommon. In case of the latter condition, it is sometimes difficult to decide whether withdrawal or larger doses are indicated. Toxic hepatitis with jaundice has been reported. I have seen at least two cases, however, in which such a condition existed from other causes. In each instance, sulfapyridine was administered in spite of the hepatitis and recovery followed. It also must be noted that sulfapyridine is a hemolytic agent. Both acute hemolytic anemia and agranulocytosis have been reported after its use. This necessitates continuous and careful blood tests. Wherever possible, at least a leukocyte count and a determination of the concentration of the drug in the blood should be made daily.

Finally, no evaluation of possible toxic manifestations is complete without considering the genito-urinary tract. Hematuria may occur, and in most instances this warrants withdrawal of the drug. At least one case has been reported in which formation of multiple renal calculi oc-

curred. Cases occasionally are encountered, also, in which urinary suppression occurs as the result of excessive precipitation of crystals in the renal pelvis. Renal function frequently can be restored satisfactorily by ureteral catheterization and lavage of the renal pelvis. An attempt should be made to maintain a sufficient intake of fluid to give a urinary output of at least 1,500 c.c. In addition, it is probable that the administration of alkalis lessens the possibility of crystalline precipitation.

Dr. Bullowa recently stated that in 500 cases in which chemotherapy was employed he had seen three instances of coronary infarction which in his opinion was the result of chemotherapy. He expressed the belief that chemotherapeutic agents do cause vascular damage and that cerebral damage may also occur.

There is always some question as to when and in what manner chemotherapy may be safely discontinued. Manifestly, with the institution of therapy, it is essential to obtain a satisfactory concentration in the blood in the shortest possible time. It is more difficult, however, to decide when, after the patient's temperature has returned to normal, it is safe to discontinue administration of the drug. To do so too soon may cause a return of fever with increased clinical manifestations. A postfebrile period of seventy-two hours has been suggested. In many instances, it is difficult to persuade the patient to continue medication this long. In my own experience, I do not remember any recurrence of fever after an afebrile period of forty-eight hours. I also have seen administration of the drug discontinued after an afebrile period of twenty-four hours without ill effect, but this cannot be depended on. Some clinicians prefer a tapering-off process when the drug is withdrawn. Dr. Bullowa and others, however, have expressed the belief that such a procedure is unnecessary and that the drug may be withdrawn suddenly after a satisfactory reaction. I personally prefer this method.

Recently, I visited some of the eastern clinics and while there had the privilege of discussion with some of the clinicians in Baltimore, Philadelphia and New York. I was particularly interested in the work of Drs. Marshall, Long and Longcope in Baltimore, of Dr. Flippin in Philadelphia, and of Drs. Bullowa and Ensworth in New York. They were all engaged in trying to determine the value of a new drug, sulfadiazine, in the treatment of pneumonia. This drug has

recently been placed on the market and is now available. A clinical study of it in a rather small number of cases of pneumonia also has been made at the Mayo Clinic. Because our supply was small, I have employed it only in those cases in which the other chemotherapeutic agents were not tolerated satisfactorily and in several instances in which nausea and vomiting were present. When treatment with sulfadiazine was instituted, the nausea and vomiting subsided and the patients went on to satisfactory recovery.

The consensus concerning sulfadiazine is that it is just as efficacious as sulfapyridine in the treatment of pneumonia and its action is similar. It is, however, definitely less toxic. In only 5 per cent of all the cases in which this drug was used have nausea and vomiting occurred. Headache also is infrequent. Rashes, drug fever, hematuria with crystal formation and psychosis have been noted, but are rare. Although hemolysis may occur, it is only with long-continued administration of the drug and is not seen until after ten days. Furthermore, it has no deleterious effect on the leukocytes. In one of Dr. Bullowa's cases, leukocytes numbered 2,000 per cubic millimeter of blood when treatment was instituted. The number promptly returned to normal during treatment.

Sulfadiazine is excreted more slowly than sulfapyridine and sulfathiazole, for which reason it is easier to maintain a satisfactory concentration in the blood. Accordingly, oral administration may be at intervals of six instead of four hours, and intravenous administration of the sodium salt, if used, could be at intervals of twelve instead of eight hours. The concentration in the blood is higher than with the other drugs. A satisfactory level is from 10 to 15 mg. per 100 c.c. The most satisfactory dosage has not been determined, but will probably consist of an initial dose of 2 to 4 gm., with doses of 1 gm. each at intervals of four to six hours.

So-called Virus Pneumonia

No consideration of the treatment of pneumonia seems complete without reference to the so-called virus type of the disease. Since 1935, many articles have appeared in the literature describing fairly large series of cases in which there was an atypical bronchial type of pulmonary consolidation and in which the infecting organism could not be determined. There were

in all cases, however, certain features in common such as a long period of incubation, a diffuse bronchial type of inflammation, and in many instances no organisms could be recovered from the sputum or nasopharynx. Furthermore, in two of Reimann's cases an unusual filtrable virus was obtained: in one, from the nasopharynx, and in the other, from the blood. In addition, Adams and Beach recently reported this disease among infants. Characteristic cytoplasmic inclusion bodies were found in the epithelial cells of the bronchi of those infants who died of the disease. Although the etiologic factor has not been determined definitely, the clinical features all lead to the assumption that this type of pneumonia is a clinical entity and that the causative factor is a filtrable virus. Fortunately, as the disease has been shown to be decidedly infectious, in most cases it runs a mild clinical course. Nevertheless, this is not always true; in a fair percentage of cases, the course is protracted and severe. In a few cases death occurs.

Recently, Long of Baltimore epitomized the salient points of virus pneumonia in a terse and graphic manner about as follows: Virus pneumonia begins like influenza with low-grade temperature and general malaise. While there is an irritative cough there is little or no expectoration. If present, it may be blood-tinged. In most instances no organisms are obtainable from it. Physical examination reveals few abnormal findings even when roentgenograms of the thorax reveal definite pulmonary infiltration. Only when the process is retrogressing are physical signs of consolidation manifest. Convalescence is frequently protracted and chemotherapy of no value.

One case has been reported in which convalescent serum seemed of value.

I have recently seen several cases that were classified as a virus type of pneumonia. In two of them, the disease was both protracted and severe. In one the constant administration of oxygen was required for three weeks. In the other, it was used almost continuously for four weeks. In neither case was chemotherapy of any benefit. In one, such medication was followed by the rapid loss of 1,500,000 erythrocytes per cubic millimeter of blood. In one case, there was considerable mental confusion, and in the other, definite psychosis occurred after the patient had become afebrile and lasted for a week. Both of these patients made complete recoveries. I cite these cases to show that so-called virus pneu-

monia is not infrequent in Minnesota and that all must be on the watch for it.

Summary and Conclusions

In the modern treatment of pneumonia, three advances have been made: (1) the use of oxygen therapy; (2) the development of specific anti-serums and (3) chemotherapy.

The most valuable chemotherapeutic agents now available are sulfapyridine and sulfathiazole. The indications are that sulfadiazine may be of even greater value.

Both 100 per cent concentration of oxygen and bronchoscopic aspiration are of great value in the treatment of pulmonary edema.

The so-called virus type of pneumonia is increasing in frequency and all physicians must be on the watch for this condition. Chemotherapy is of no value in its treatment. Convalescent serum may be proved of value. At present, oxygen therapy is the treatment relied on in this type of pneumonia.

THE USE OF CHILLED BLOOD, BLOOD PLASMA AND SERUM

THOMAS H. SELDON, M.D., M.S. (Anes.), and JAMES T. PRIESTLEY, M.D.

Rochester, Minnesota

Chilled Blood

AT THE turn of the present century, Landsteiner discovered three of the four blood groups. Decastello and Sturli added the fourth group in 1902. As a result of these discoveries, the incidence of severe reactions to transfusion has decreased greatly. Today, transfusion of blood is an accepted and valuable therapeutic measure.

In April, 1914, Hustin of Brussels published an account of the use of a mixture of sodium citrate and glucose as preservative agents for blood. Agote^{1,2} of Buenos Aires also used sodium citrate as a preservative agent; the first notice of his use of sodium citrate appeared on November 14, 1914. Lewisohn published his method using sodium citrate in January, 1915. Weil and Rueck separately presented their data concerning the use of sodium citrate early in this same year.

Rous and Turner, in 1916, found experimentally that preserved erythrocytes could be transfused and that they continued to function normally. Robertson, in 1918, advocated the storage of blood; dextrose and sodium citrate were used as the preserving agents.

Lundy and associates,¹⁹ used stored chilled blood in 1935. The blood stored in the refrigerator was for emergency purposes or was blood withdrawn from relatives to be used at a later time when the relatives would not be available as donors. The "blood bank" was described by Fantus in 1937.

The obvious advantages of having chilled blood of a known blood group which is negative to serologic tests for syphilis always available are well known. DeGowin and Hardin advised the addition of glucose in order to lengthen the possible storage time of the blood. They found that hemolysis was present in any mixture after five days, but that the addition of glucose kept hemolysis minimal for thirty days.

There is a marked shift of the potassium ions from the erythrocytes to the plasma after five days of storage.²⁹ Prothrombin decreases with the storage of blood.³⁶ Bull and Drew pointed out that the number of leukocytes decreased 50 per cent in the first twenty-four hours of storage and that after sixteen days of storage the leukocytes practically were disintegrated. Levine demonstrated by means of the specific factors M and N that cells stored three, ten and fourteen days have a survival time of eighty, sixty and twenty days, respectively, after transfusion, whereas freshly drawn cells have a survival time of ninety-five days or more after transfusion.

From the Section on Anesthesia (Seldon) and the Division of Surgery (Priestley), The Mayo Clinic, Rochester, Minnesota.
Read before the annual meeting of the Minnesota State Medical Association, St. Paul, Minnesota, May 27, 1941.

Injectations of chilled stored blood for the possible beneficial effect of leukocytes or platelets or to overcome a prothrombin deficiency are of questionable value.

In the annual report for 1940 of the Section on Anesthesia of the Mayo Clinic,²⁰ it was disclosed that the majority of blood used in transfusions was blood that had been in the refrigerator for one or more days. The incidence of reactions was found to be slightly less when chilled blood was used than when blood was withdrawn and used immediately. The advantages of always having blood in storage have been pointed out by many writers. It is a good plan to have a minimal yet adequate emergency overnight supply always available. In this way the supply can be replenished almost daily, the chilled blood never becomes many days old and patients who are in need of leukocytes or who have a deficiency of prothrombin can receive a transfusion of reasonably fresh blood which still has a satisfactory percentage of the constituents of freshly drawn blood. If an emergency transfusion is required in cases of severe hemorrhage, the patient receives the benefit of little delay, as blood from universal donors always is on hand.

Plasma and Serum

In 1812, Legallois suggested the preparation of some artificial fluid medium which could be used for perfusion experiments. The need for a satisfactory blood substitute is apparent and has stimulated many workers in various countries. An ideal blood substitute would be one that is readily available, stable for long periods, easily stored, transportable without damage to its properties, and furthermore one that will remain within the circulatory system and will not produce any untoward reactions.

Crystallloid solutions, although used extensively as blood substitutes, are not entirely satisfactory because they leave the circulatory system. Solution of acacia was used frequently during the War of 1914 to 1918, but it is not used as much now as formerly because of the ready availability of blood and plasma.

In 1918²⁷ it was considered that infusions of serum or plasma combated hemorrhage. Serum was procured by allowing blood to clot and then withdrawing the fluid portion. To obtain plasma, whole citrated blood is either centrifuged or al-

lowed to stand several days in order to allow the cells to settle out. The supernatant blood plasma is then drawn off. Large amounts of serum or of plasma may be pooled.

Levinson and co-workers stated that large amounts of pooled serum may be administered without untoward reactions. Other writers⁴ do not share this opinion. Plasma may be stored in either the liquid or powder form for long periods.³⁴ If large quantities of plasma need to be stored for long periods or for ease in transportation, the process of drying plasma has proved its value in saving of storage space. When the powdered plasma is redissolved, it seems to be as beneficial therapeutically as it was in the primary liquid state.

There are various ways of drying plasma, for instance, the lyophil process, the cryochem-process or the method whereby it is dried at an increased temperature.^{8,10,11} Blood plasma, regardless of the donor's blood group, may be given to any recipient, regardless of his blood group.³² The pooling of plasma from donors of different blood groups seems to suppress the iso-agglutinins. Amberson³ stated that blood plasma is nonantigenic and therefore less liable to cause anaphylactic reaction.

Plasma is being used in an increasing number of conditions.³¹ It may be that investigations being carried on will reveal that blood plasma may replace the use of whole citrated blood in many conditions in which blood is being used now. At present, however, the more common cases in which plasma is used are secondary shock, hemorrhage, burns, edema and states of hypoproteinemia.

Strumia³³ and his associates made the statement that plasma appears to be the ideal material for the permanent reestablishment of proper circulation in cases of secondary shock. Because of the content of protein and the high colloidal osmotic pressure, blood plasma does not leave the circulation as crystalloid solutions do; therefore, it is possible to regulate the volume of circulating blood more readily when blood plasma is used. Mahoney pointed out two advantages of using plasma in cases of secondary shock, namely, lack of necessity of blood grouping and dilution of the hemoconcentration. It was also stated that in the treatment of experimental shock in the animal, the use of lyophilic plasma was more efficacious for raising the blood pressure than

blood, physiologic solution of sodium chloride or solution of acacia.

In cases of shock following severe hemorrhage, the loss of circulating erythrocytes is of minor importance if the volume of circulating blood is kept at a proper level. The fatality accompanying or following acute hemorrhage is not due to the loss of erythrocytes but to inadequate circulation, tissue anoxemia, increased permeability of capillaries and shock caused by the loss of circulating fluid.^{17,23} Sudden massive hemorrhages produce oligemia and primary shock. The chief need in this condition is to replace fluid in order to maintain the volume of the circulating blood. Composition of the fluid is unimportant. Hoitink demonstrated that a 0.9 per cent solution of sodium chloride was as good a substitute for blood in this condition as any other fluid. However, secondary shock following severe hemorrhage demands the addition of a more permanent fluid because of the loss of plasma through the increased permeability of capillaries. Levinson and associates¹⁷ advocated serum; others are of the opinion that plasma is the fluid of choice. If whole blood were readily and quickly available, it probably would be the best restorative in cases of severe hemorrhage, but if whole blood is not available, either serum or plasma is a valuable therapeutic agent in maintaining the volume of circulating blood necessary for life.

Minot and Blalock described the changes of the volume of plasma and concentration of protein in a dog during development of circulatory failure following a burn. Thirty-two per cent of the plasma volume and 35 per cent of the plasma protein had been lost at the end of six hours; there was a corresponding hemoconcentration. These changes continued until 61 per cent of the original volume of plasma and 50 per cent of the total circulating protein remained. These authors stated that blood plasma is probably the fluid of choice for the restoration of the plasma volume.

Starling³⁰ demonstrated many years ago that the osmotic pressure of plasma crystalloids, although large as compared with plasma proteins, still is of minor importance in keeping fluids within the blood vessels. As the concentration of plasma protein falls from its normal level of 7 to 7.5 gm. per 100 c.c., the osmotic pressure exerted by the plasma is reduced and fluid will

leave the vascular system and produce, at first, a latent and later an evident edema. It has been demonstrated that plasma administered in such cases will decrease edema.

In cases of hypoproteinemia, Ravdin disclosed that repeated small transfusions of plasma over a long period are more efficacious than large transfusions of plasma within a short period.

Conclusions

Chilled blood has proved of value, for the percentage of reactions has been demonstrated to be slightly less than when fresh blood was used for transfusion. Blood plasma and serum seem to be satisfactory substitutes for blood in certain cases of secondary shock, hemorrhage, burns and so forth. Either of these may be stored readily and transported easily. Both may be dried, powdered and redissolved for use. The results obtained from the transfusion of the redissolved powder seem to be favorable to the patient. Continued investigation and repeated clinical use of these agents should render more data available in regard to their respective merits.

PHARMACOLOGICAL SHOCK THERAPY AT ST. PETER

GEO. H. FREEMAN, M.D., A. S. NISSEN, M.D., and E. W. MILLER, M.D.

St. Peter State Hospital, St. Peter, Minnesota

SINCE the introduction of pharmacological shock therapy by Sakel and von Meduna there have been many reports of its use in this country and abroad. While we do not have a large number of patients to report on, we should like to add ours to those in the literature.

St. Peter State Hospital began insulin treatment in December, 1936, approximately six months after its introduction in this country and we have by now treated 160 individuals. Metrazol treatment was first used at St. Peter in December, 1937, and we have to date treated ninety-nine.

The criteria for our selection of those to be treated have changed. In the beginning only schizophrenics were treated either with metrazol or insulin, but in recent months we have treated these patients mostly with insulin and reserved metrazol treatment for manic-depressive and involutional psychotics. At first we paid little attention to the duration of the disorder, but later as we learned of the importance of the time element from our own and others' experience, we attempted to limit treatment to those of shorter duration. We have treated a number of considerable duration at the insistence of relatives, even

though we felt that the prognosis was not particularly good.

A patient selected for insulin or metrazol therapy receives a careful physical and laboratory examination. In ninety cases we have secured sugar tolerance tests before and after therapy for comparison. We plan to report an analysis of these figures at a later date.

When therapy is started, the fasting patient is given, early each morning, a progressively larger amount of insulin until shock doses are obtained. They are permitted to remain in shock one to one and a half hours and termination is by either orally or intravenously administered glucose.

In contradistinction to most hospitals we use a diet of fixed caloric value. We have felt that this is advisable in that the insulin dosage can be better regulated and with the relatively restricted diet (1600 calories) such as ours, smaller amounts of insulin are necessary to produce hypoglycemic shock. Despite the limited caloric intake, ninety-nine of our patients gained weight.

The average number of shocks administered was approximately sixty and the average dose for men was eighty-one units of insulin and for women sixty-seven.

The detailed results are shown in Table I.

Read before the annual meeting of the Minnesota State Medical Association, Saint Paul, Minnesota, May 26, 1941.

m—males in hospital, M—males at home, f—females in hospital, F—females at home.

From this it is seen that eighty-two men and seventy-eight women have been treated. One hundred and forty-three suffered from dementia precox and eleven from manic-depressive psychoses.

Of the one hundred and forty-three dementia

precox patients treated, seventy-one or 49 per cent are at home, and of these thirty-six are markedly improved. Of the eleven manic-depressive psychotics, ten are at home markedly improved and apparently recovered. The eleventh died of pulmonary tuberculosis.

As others have reported, there is a significant difference in results obtained in dementia precox depending on the duration of the disease. For instance, of the thirty-five dementia precox cases of less than six months' duration, twenty-nine are at home and twenty-one of these are markedly improved. Of the twenty-four of six to twelve months' duration thirteen are at home with seven markedly improved. In cases of from one to two years' duration thirteen out of twenty-five are home and six are markedly improved; in those of over two years' duration sixteen out of fifty-nine are home but only two are markedly improved. It is noted that the largest differences in results occur between the group of less than six months' duration and those of six to twelve months and again between the one to two years' duration group and that over two years. There is but slight difference between results obtained in the six to twelve months' classification and the one to two years' classification.

Of the seventy-four male dementia precox patients, thirty-eight are at home and of these fifteen are markedly improved; while of the sixty-nine female dementia precox patients thirty-three are at home and twenty-one markedly improved. There is a significant difference in the number of markedly improved in each group. This is probably explained, at least partially, on the basis of the difference in duration, as the median duration for male cases is forty-four weeks and for the female twenty-eight weeks.

We have had no deaths from insulin therapy. We have had one patient in which we felt that insulin treatment was a factor in the exacerbation of a latent pulmonary tuberculosis which eventually resulted in death. We have had sixteen cases of prolonged coma during insulin treatment. We made this diagnosis if after the usual amount of carbohydrates plus the intravenous injection of at least 50 c.c. of 50 per cent glucose the patient remained comatose. The condition is characterized by normal or elevated blood sugar, coma, motor irregularity, elevated temperature and respiratory irregularities. The duration of the coma varied from a few hours to about forty-eight hours and all eventually recovered.

Dr. Rossen of the Hastings State Hospital has kindly allowed us to include the results of his experience with insulin therapy. His results are of particular value in two respects: (1) he has

used a control group as far as technique is concerned; and (2) all his patients, except one, have been institutionalized for five or more years. His report includes eighty-four patients, forty-six receiving insulin and thirty-eight controls. His method of controlling the technique was as follows: Both groups of patients were on the same ward, received the same diet, the same nursing attention, and differed only in that one group received insulin and the other group received injections of sterile water. His results of insulin-treated patients are as follows: 72 per cent unimproved, 15 per cent moderately improved and 13 per cent greatly improved. Of the controls, 97 per cent unimproved and 3 per cent moderately improved.

Metrazol is given biweekly to the fasting patient. Various precautions are taken, such as placing a towel in the mouth to avoid biting the tongue, restricting the movements of the extremities and preventing extreme opening of the mouth to avoid dislocations.

The initial intravenous dose is 4 c.c. of a 10 per cent solution. If this fails to produce a convulsion in three minutes, a second dose of 5 c.c. is given. (We wait three minutes as this is the longest interval between injection and convulsion we have encountered.) If the second attempt is also unsuccessful, a third dose of 6 c.c. is given in another three minutes. With one exception this is the largest amount we have found necessary to produce the initial convulsion. The average number of convulsions induced in the men was twenty-one and in the women eighteen.

We have never been unable to produce a convulsion, although successive treatments commonly require an increased amount of metrazol. The largest intravenous dose necessary has been 11.5 c.c. In a few women the drug was given intramuscularly because of unsuitable veins. In these the initial dose was 8 c.c. not repeated the same day, and increased 2 c.c. if the preceding injection was unsuccessful. The largest intramuscular dose necessary has been 30 c.c. The seizure, if it occurs, takes place from ten to forty-five minutes later. We have observed as many as three convulsions, several hours apart, following a single intramuscular use of the drug.

Two patients with dementia precox were given camphor intramuscularly in February, 1938. Both were paroled home as moderately improved, one

after having eighteen convulsions and the other after seven. Both relapsed and are in other state hospitals at present.

give the intravenous injection. Following the suggestions of Bennett we have given hyoscine hydrobromide one hour before treatment in doses

m—males in hospital, M—males at home, f—females in hospital, F—females at home.

Some degree of apprehension regularly appears after the first one or two treatments. In a few patients this has been severe enough to provoke sufficient resistance to make it difficult to

of 1/150 to 1/100 grain to three patients. This has materially helped in allaying anxiety, producing greater coöperation, and has not affected the dosage required to produce a convulsion.

As seen in Table II twenty-nine men and seventy women have received metrazol to date, of whom forty-one are now at home. Four of these, all in the schizophrenic group, were considered unimproved when they left the hospital, and released because their relatives were able and willing to provide the degree of supervision that seemed necessary. Two were thought to be only slightly improved when they left, while the remaining thirty-five were considered moderately to markedly improved. When we examine only the thirty-five whose duration of symptoms was one year or less, twenty-seven are at home, six in the hospital, and two dead. Of those at home in this group, two were considered unimproved, two only slightly improved, and the rest moderately or markedly improved.

In comparing the affective and schizophrenic groups we find that of twenty-eight patients treated in the former group, twenty are at home, seven still in the hospital, and one dead; while in the latter or schizophrenic group, nineteen are home (four unimproved) out of a total of sixty-eight treated, forty-seven are in this or other hospitals, and two are dead.

Nine patients with involutional melancholia received metrazol. One of these did not complete the treatment as she died of pneumonia. One patient is still here but ready to leave as soon as we find a place for her. The remaining seven all went home as markedly improved.

Conspicuously poor results are to be noted in the schizophrenic group whose symptoms were of two years or longer duration. Of the forty who fell in this group, thirty-five are still hospitalized, four at home (two of these unimproved) and one is dead.

Three patients have died from causes not related to metrazol therapy.

Twenty-two of the patients receiving metrazol had previously been given insulin with no improvement. Eight of these are home and the remaining fourteen are unimproved.

A few patients who were markedly assaultive and disturbed showed considerable improvement in this respect although there was no essential change in their mental condition and they are listed as unimproved.

Dislocation of the jaw has been the most frequent complication and in all cases has been easily reduced. Dislocation of the shoulder occurred once, was readily reduced, and did not interfere

with subsequent therapy. Pain in the thoracic or lumbar region of the spine is an infrequent complaint. If it persists longer than several days we secure x-rays but have not encountered a definite compression fracture of the vertebrae.

It is to be noted that we have not called any of our patients recovered. However, the markedly improved group, especially in so far as the affective psychoses are concerned, can be considered clinically recovered. In the dementia precox patients the markedly improved have no clinical symptoms and most of them are making the same social adjustment as before the onset of their psychosis. In the slightly improved group the improvement has been mostly that of a better hospital adjustment and there has been essentially no change in their fundamental mental condition. In the moderately improved group the patients superficially approach normal but psychiatric examination reveals some degree of mental abnormality. Our results are as of our last knowledge of the patient, that is, at the time of parole or of our last follow up report. Our follow-ups were either in the nature of letters to the patients' relatives or of parole agents' reports. It is recognized, of course, that the condition of patients as reported by relatives is not particularly accurate. Of the eighty-five insulin patients who are now home we have had follow-ups on fifty-seven of them, and of the forty-one metrazol patients at home we have follow-ups on twenty-one.

We have counted as relapses all those who were markedly or moderately improved at the end of treatment and have subsequently regressed to an unimproved state. On this basis in the insulin series we have had eleven relapses in the men and sixteen in the women and in the metrazol series one man and two women. The difference in the number of relapses is explained at least partly by the fact that we do not have as many follow-ups on the metrazol cases and that metrazol treatment was started here a year later than insulin treatment.

The greatest defect in our data is the lack of a control group. A control group can either be controlled as to technique or as to selection of cases. The latter, of course, is most important. Because of this lack of a control group we cannot adequately answer the question "what would have happened to these patients if they had not received treatment?"

HEMATOLOGY OF PERNICIOUS ANEMIA

CHARLES VANDERSLUIS, M.D.

Bemidji, Minnesota

WE ARE all acquainted with the classical symptoms of pernicious anemia, some of which are presented by patients with anemia due to other causes. What distinguishes pernicious anemia, however, is that it is a generalized disturbance with the phenomena of anemia (due to the lack of the so-called intrinsic factor in the gastric secretions) shared with glossitis, gastrointestinal manifestations, graying of the hair, and central nervous system disturbances.

There is a tendency, on the part of a busy practitioner, to avoid laboratory work unless trained assistance is available. However, the diagnosis of the particular type of anemia is important. Suppose one encounters a patient with a severe anemia, institutes liver, iron, and vitamin therapy, and finds there is incomplete response to this material. Then, it is necessary to retrace the steps in diagnosis with an altered blood picture. Possibly one will be forced to wait until the effects of treatment have worn off before being able to name the disease.

A middle-aged patient encountered with signs of anemia and a red count below two million and not suffering acutely from it, possibly has pernicious anemia. If, as a result of repeated red cell counts and hemoglobin determinations, the color index is found to be greater than one, this possibility is strengthened. Add to this a fasting gastric content with no free hydrochloric acid after histamine injection, and the diagnosis is even more likely. In order to make our decision more air-tight, however, it is wise to go further because this patient might be suffering from carcinoma of the stomach, leukemia, or cirrhosis of the liver.

In pernicious anemia there is a decrease in all of the formed elements of the blood—leukocytes, red cells, and platelets. To examine the qualitative changes in these cells, one should make several blood smears on alcohol-cleaned slides. After a Wright's stain, one will see a reversion to the fetal type of blood with large erythrocytes well filled with hemoglobin (macrocytes) and their megoloblastic precursors. There

will also be seen a great variation in the size of these cells (anisocytosis), irregularity in shape of some of them (poikilocytosis), and relative blueness of scattered red cells (polychromatophilia). One may see nucleated red cells (normoblasts). Some of these changes are signs of blood regeneration and others of degeneration. The signs of regeneration are most frequent during beginning remission and quite scarce during severe relapse. On the other hand, signs of degeneration are always present, being most marked during relapse. It is thought by most that the basis of the disease is that of failure of red blood cell maturation and by a few that the changes are attributable to increased blood destruction. Be that as it may, the red cells give us valuable information about the state of the patient's disease. Anisocytosis and polychromatophilia occur in rapid production of red cells. Before the developing red cell takes on hemoglobin, it contains a basophilic spongioplasm. The mixture of hemoglobin and the remains of basophilic spongioplasm takes a purplish stain, rather than the lighter red. Nucleated red cells are young, and their presence usually indicates blood regeneration. The cytoplasm of these cells may vary from basophilic, indicating no hemoglobin, to orthochromatic, indicating normal hemoglobin content. Poikilocytosis indicates degeneration of the affected cells and is most marked in severe anemias, notably pernicious anemia in relapse.

An increase in reticulocytes also indicates blood regeneration. Supravital staining is necessary for their recognition. A thin smear of 1 per cent brilliant cresyl blue in 100 per cent alcohol is made on a slide. After this is dry, a thin blood smear is made over it and immediate drying is prevented by placing the slide in a closed Petri dish over wet filter paper, and allowing it to stand five minutes. Young red cells which have not lost all their spongioplasm will be stained by this procedure, the strands of spongioplasm taking the stain. Normal blood contains 1 to 3 per cent of reticulocytes, and pernicious anemia in relapse shows similar percentage. Seemingly, this is a point against increased blood destruction, because in congenital hemolytic jaundice there is

Read before the annual meeting of the Northern Minnesota Medical Association, St. Cloud, Minnesota, August 15, 1941.

a considerable reticulocyte increase. Since polychromatophilia and reticulocytosis increase with remission of the disease, they are important in judging the effectiveness of therapy and will be referred to again.

Macrocytosis, or the predominance of large red cells well filled with hemoglobin, has been referred to before. There is a simple volumetric method to prove whether or not this is present—a determination of mean corpuscular volume. Put 10 c.c. of blood into a 15 c.c. graduated centrifuge tube containing 2 c.c. of 1.4 per cent sodium oxalate solution. Mix this by inverting and centrifuge for an hour at 2,500 revolutions per minute. Read the volume of packed red cells directly off the tube and record as the number of c.c. per 1,000 c.c. of blood. In order to determine the mean corpuscular volume in cubic microns, simply divide this volume of packed red cells by the red count in millions. Normal limits vary between 80 and 94 cubic microns, and the value for pernicious anemia blood will be around 130 cubic microns. This is a valuable calculation, but obviously the red count must be accurate.

Considering the white cells in the count and smear, one will find a leukopenia and a relative lymphocytosis, indicating an absolute decrease in granulocytes. Among these remaining granulocytes will be found a general increase in segmentation of the nuclei of the neutrophils and hypersegmentation of the nuclei of a few, the latter finding characteristic of pernicious anemia, although not absolutely diagnostic. This leukopenia may persist in the face of rather severe infection.

Megaloblasts are sometimes found in the smear of pernicious anemia blood, as well as in other cases of severe anemia. These are primitive nucleated red cells usually larger than normoblasts, containing a varying amount of hemoglobin in the cytoplasm. They are an independent cell line according to Downey, which is in no way related to the normoblasts except through the primitive myoblast. Their appearance is a sign of reversion to the embryonic state of blood formation and of severe demands upon the marrow, according to Downey. In the pernicious anemia patient megaloblasts may be absent from the blood stream, but they will always be found numerous in the marrow.

This leads to the matter of investigation of the bone marrow by sternal puncture, which

will be a help in diagnosis. One remembers that the red cells and granulocytes are produced normally in the red marrow situated in the vertebrae, ribs, sternum, diploë of the bones of the skull, and the proximal epiphysis of the femur and humerus of the adult. In the newborn, the cavities of all the bones are filled with red marrow. With advancing age, yellow fatty marrow replaces the red in all the cavities except those mentioned above. In pernicious anemia there is a reversion to the fetal state, and yellow marrow is replaced by red. In this so-called hyperplastic marrow, blood formation is not very effective. There is a slight increase in cells resembling myeloblasts but few resulting myelocytes. Megaloblasts are numerous, partially replacing normoblasts. There is a question whether these megaloblasts ever do form fully developed erythrocytes in relapse. These megaloblasts and myeloblasts are collected into syncytial masses, resembling the blood islands of embryonic blood formation. Under liver therapy there is a rapid maturation of the megaloblasts to erythrocytes, and no new megaloblasts are formed. Along with this, there is normoblastic hyperplasia. In complete remission the marrow is entirely normal. In a case which does not respond to liver therapy, the bone marrow may be aplastic and its examination lend some information. Erythrocytes in all stages would be few and lymphocytes would be comparatively numerous.

Because of the above-mentioned defects in blood regeneration in pernicious anemia, hemoglobin destruction is active. Seemingly the best explanation is that hemoglobin is formed in normal amount but is not used by the immature red cells. As a result of its excess, it is broken down in the usual manner to hematin and globin, these products appearing in increased amounts in the blood, just as they would in case of increased blood destruction. For an estimation of the extent of this, one must resort to chemical methods.

Bilirubin and hemosiderin are the main products of the breakdown of hematin. Bilirubin, an iron-free product, freely soluble in blood plasma and tissue fluids, is excreted mainly in the bile, some normally remaining in the blood serum to give it its light brown color. Bilirubin in the intestine is reduced to urobilinogen by bacterial action. Part of the urobilinogen is excreted in the stool and part absorbed into the blood stream, from which reëxcretion by the liver in the bile occurs. Normally, only very small amounts of

urobilinogen appear in the urine. Hemosiderin, an iron-containing pigment, is formed only intracellularly by phagocytes and identified by the Prussian blue reaction with potassium ferrocyanide and hydrochloric acid. This is a test for ferric iron.

The excess bilirubin formed as a product of this destruction of hemoglobin circulates in the blood, causing a yellow skin and subcutaneous fat and a yellowish blood plasma. This slight icterus causes an increase in the icterus index, from a normal of 4 to 6, to around 9. Therefore, a pale blood serum is against the diagnosis of pernicious anemia. So-called secondary anemias, of non-hemolytic origin, give a low icterus index. As a result of increase of bilirubin in the blood there is an increased excretion in the bile, resulting in an increased amount of urobilinogen formed in the intestine. An increased amount of urobilinogen is absorbed into the portal circulation and excreted by the liver in the bile. In case of overwhelming amounts of urobilinogen in the blood stream or of diminished liver function, an increase of urobilinogen may appear in the urine. Thus, in pernicious anemia, an increase of urobilinogen is always noted in the twenty-four hour stool specimen but no increase of urine urobilinogen occurs unless there is unusual hemoglobin destruction or diminished liver function. In line with the efforts of the body to con-

serve iron, the hemosiderin resulting from the excess hemoglobin destruction is deposited in the liver, spleen, and kidneys, and these granules often can be seen in post-mortem sections and identified positively by the Prussian blue reaction. When therapy has been started, these iron deposits are taken up and used by the bone marrow for maturation of the megaloblasts.

Keeping in mind the macrocytic nature of the anemia, the leukopenia with relative lymphocytosis, and the megaloblastic hyperplasia of the bone marrow, a clinching proof of the hematological identity of this disease is reticulocyte response to liver therapy. Give three daily injections of liver and observe the daily reticulocyte count. This count will rise by the third day and continue to increase until about the sixth day, along with a rise in red count and a slower increase in hemoglobin. The cases with the lowest initial red counts will show the greatest reticulocyte response, apparently because of the maturation of the large number of megaloblasts in the bone marrow. Hemoglobin destruction is also lessened, as is demonstrated by a lessening of the urobilinogen in the stool and a lowering of the icterus index.

In the above outline we have tried to mention the important features of the hematology of pernicious anemia. We wish to leave the impression that the clinical features of this systemic disease are of equal importance.

TUMORS OF THE PITUITARY GLAND

RICHARD R. CRANMER, M.D.

Minneapolis, Minnesota

INTEREST in ductless glands in general, and the pituitary gland in particular, has been on the increase during the last decade. We have known for several decades the effect of the hypodermic injection of the extract of the posterior lobe. We have also known that growth has been influenced largely by hormonal agents, generated by the pituitary gland, and more recently it has been discovered that gonadatropic hormones are generated by the anterior lobe of the pituitary gland (prolan A and prolan B). Still more recently, it has been proved that there are

a great number of other hormones thus generated, such as lactogenic hormone, thyrotropic hormone, diabetogenic hormone, pancreatotropic hormone, ketogenic hormone, adrenotropic hormone, parathyrotropic hormone, and others.

It was, however, the gross lesions of this small structure which first attracted attention, and only then was it realized what a wealth of interesting information regarding its function was lying there waiting to be extracted.

The anterior part is glandular in structure, and is developed, embryologically, from Rathke's pouch, an out-pouching of pharyngeal epithelium.

Read before the Minneapolis Surgical Society, May 2, 1940.

The stalk, connecting this part of the pituitary with the pharynx, disappears, but embryonal rests may remain, and from these rests rare tumors, usually squamous-cell carcinomata, may develop in any portion of the vestigial track. The anterior part of the pituitary gland envelopes the posterior part in very much the same way as one's hand holds a tennis ball.

The posterior part, or the nervous structure, is developed from an entirely different source. It is developed from a down-growth from the floor of the third ventricle, and remains connected with its site of origin by a slender stalk or infundibulum. Through the infundibulum passes a narrow channel, which, in the opinion of some men, as Herring and Cushing, conducts the extract of the posterior lobe into the third ventricle, from where it is finally absorbed. The posterior portion is singularly uninteresting in structure. No nervous elements can be distinguished. It is composed of a mass of neuroglia with here and there a few small cells. No one would suspect from a study of this inert-looking structure that an extract prepared from it would be capable of producing the most dramatic physiological effects.

Microscopically, the anterior lobe, on the other hand, produces a very interesting picture. It is definitely granular in structure. It is made up of two main types of cells: chromophil and chromophobe. The former, which are by far the more numerous, have a granular cytoplasm which stains deeply. The latter, often known as the chief cells, which are few in number under normal conditions, are of small size and possess a scanty cytoplasm which stains faintly. The chromophil cells may again be divided into eosinophil and basophil, according to the staining reaction of their granules. If there develops an urgent demand for pituitary secretion, as in pregnancy, the small chromophobes increase in size but remain chromophobe and yield up their secretion as soon as formed. During pregnancy, sometimes the weight of this gland is doubled, such increase in weight being due, almost entirely, to a hyperplasia of the chromophobe cells.

At the very outset, one is faced with one remarkable fact: the anterior portion is to every appearance glandular, being made up of different kinds of epithelial cells which vary in their proportion under different physiological conditions, and yet an extract of this part is absolutely without any physiological effect. On the

other hand, the extract of the inert-looking posterior lobe produces, as before stated, the most startling results. This substance excites a contraction of plain muscle throughout the body, raising the blood pressure to a marked degree through a general arterial contraction (but relaxes the renal vessels, thus producing diuresis), also causes the uterus to contract violently, stimulates the secretion of milk, and, by greatly lowering the sugar tolerance, causes sugar to appear in the urine. Although it is not possible to accurately separate the functions of the two portions of the gland, we may say that the anterior lobe is concerned with growth, particularly the growth of the skeleton and the development of the sexual organs, whereas the posterior lobe appears to be concerned with carbohydrate metabolism, and, therefore, with the development of fat.

Pathological manifestations of pituitary disease may be grouped under the headings of hyperpituitarism and hypopituitarism. Hyperpituitarism can be a result of diffuse hyperplasia of the eosinophilic cells or of the basophilic cells, or of eosinophilic or basophilic or chromophilic adenomata. The effect upon the body is distinctly different in each.

Considering first hyperplasia of the eosinophilic cells, or eosinophilic adenoma, there are the following possibilities.

1. Hyperactivity, before ossification is completed, invariably results in some degree of gigantism. This is the type of individual that is exhibited in the side-shows of circuses. Every giant, at some stage, shows hyperplasia of the pituitary. This, however, at once introduces us to the fact that pure pituitary lesions are rare. Hyperfunction is often followed by hypofunction. A giant frequently shows symptoms of hypopituitary function, such as high sugar tolerance or sexual impotence. If the activity of the pituitary is maintained, there will be a low sugar tolerance and glycosuria. Many giants die of diabetes. When hyperfunction is still in evidence, the pituitary may be found to be much enlarged and the sella turcica shows a corresponding expansion, which can often be readily recognized by means of radiographs. Later in the disease, the pituitary may be greatly shrunken or converted into a cyst, but the telltale bony changes bear evidence of the former hyperplasia.

2. Hyperplasia, after ossification is complete, results in deformity of bones commonly called

acromegaly. This condition, first recognized by Pierre Marie in 1886 to be due to a disorder of the pituitary body, is characterized by great enlargement of the hands and feet, the bones in the face and lower jaw. Both the bones and the soft parts of the hands and feet participate in the enlargement. Symptoms of giantism may be present, indicating that the period of pituitary overactivity has antedated the cessation of ossification. In a word, then, giantism is the result of hyperpituitarism developed before ossification is complete. Acromegaly or deformity of the bones is the result of hyperpituitarism developing after ossification is complete, the cause of each being eosinophilic adenoma, or eosinophilic hyperplasia of the anterior lobe of the gland. The diagnosis of acromegaly is readily made when the changes are at all pronounced. The face is large, the frontal sinuses are prominent, the eyes are deep-set, the lower jaw is heavily undershot so that the lower teeth project beyond the upper ones. The teeth themselves are widely separated. The lips are thick, the tongue hypertrophied. The skin is thick and deeply porous, the hands and feet are huge and clumsy. One of the most characteristic features is the presence of exostoses on the phalanges of the fingers and a tufting in the terminal phalanx. This forms a striking picture on the x-ray plate.

The size of the pituitary adenoma, or the hyperplastic gland itself, can be frequently determined by x-ray of the sella turcica. There is destruction of the base of the sella, in addition to an upward distention of the membrane covering the pituitary.

Hypo-activity of the pituitary presents the Fröhlich's syndrome. The appearance of the individual suffering from hypo-activity of the pituitary is generally that of infantilism, in which there is a notable absence of development of the skeleton and the sexual glands and the secondary sexual characteristics do not appear. In addition to that, there is usually the development of obesity and high sugar tolerance. There is usually a mental torpor associated with this condition, with the patient ever ready to sink into slumber.

In diffuse hyperplasia of the basophilic cells, or basophilic adenoma, the picture is entirely different. Here we have Cushing's syndrome. This is characterized by amenorrhea in the female and sexual impotence in the male. Hirsutism develops on the face and trunk of females and the males of pre-adolescent age. The hair on the scalp is

thin, there is a loss of feminine curves in the female, and the voice becomes masculine. There is hypertension, a hyperglycemia, and an extreme exhaustion in some cases. It is further characterized by painful obesity of the face, neck, and trunk, but not the extremities.

This same syndrome is seen in tumors in other parts of the body, such as cortical tumors of the adrenal gland and in arrhenoblastoma of the ovary.

Diagnosis of primary hypophysial tumors is based on: (1) endocrine disturbances; (2) changes in the bones, as evidenced by radiographs, such as enlargement and destruction of the sella turcica, and occasionally an intrasellar shadow in the radiographs; (3) changes in visual fields and eyegrounds; (4) headaches and other signs of increased intracranial pressure.

The treatment of these tumors consists of surgical treatment and the use of the x-ray.

Dandy states that there are two approaches to the tumor: (1) the nasal route, and (2) a right or left frontal approach. He dismisses the operation via the nasal route as impractical and dangerous, and states that it can never be otherwise because of the route through which the operation is carried on. He uses avertin anesthesia, administered rectally, and the frontal approach is made either on the right or on the left side. The side with the poorest vision is always chosen because in a certain number of cases it is necessary to sever one of the optic nerves. If vision is equal on both sides, a right-side approach is always preferred. The incision is above the hairline, and the scalp, bone and dural flap are turned downward. The frontal lobe is gently retracted with a spatula, exposing the chiasmal region. The steps to be taken for actual removal of the tumors then depend on several anatomical factors, as the length of the optic nerves, the location of the tumor in relation to the optic nerves, the size, shape and position of the tumor, and the strength of the tumor's capsule. To meet all of the above variations, three procedures are necessary: (1) removal of the tumor between the intact optic nerves; (2) removal of the tumor after severing one optic nerve; (3) removal of the tumor after resection of part of a frontal lobe. He states that these procedures, with few exceptions, will permit a complete, or almost complete, removal of the suprasellar portion of the tumor as well as that part which lies in the sella.

In the cases that I present tonight, the x-ray

treatments were used in both, with some resulting improvement, and, in one case, a redeposition of calcium into the sella, resulting in narrowing of it.

The first case, V. W., is a dentist, forty-five years of age.

His family history gave no important information. He had had sinus trouble for the past fifteen years.

About ten years ago the patient's dentist noticed that

This patient received two series of x-ray treatments using the 400 Kv. machine. The first was a series of 18 treatments, and the second, a series of 20 treatments, alternating right and left lateral fields over the pituitary. He was given then about 1900 roentgen units, measured in air, to each field; 1900 roentgens are equal to one erythema. The treatments were given daily with an interval of two months between the two series.

A radiograph of his skull, taken two years after the

Fig. 1. Radiograph showing the deep frontal and maxillary sinuses, the irregular thickening of the skull bones in general, and an almost totally destroyed sella turcica.

Fig. 2. Radiograph showing the sella turcica rather plainly and without complete destruction of the walls of the sella. The frontal and the maxillary sinuses also are deep. Some irregularity in the thickness of the skull bones is also indicated here.

the mandible was increasing in size so that the lower dental ridge did not meet the upper. He began to have headaches and later noticed that his hands and feet were enlarging.

In the summer of 1937 a progressive numbness and clumsiness of the fingers made it difficult to use his dental instruments. It became impossible for him to handle small parts such as inlays and he discontinued practice.

By this time the prognathism and enlargement of the supraorbital ridges had reached large proportions. There was no associated visual disturbance. The lower jaw advanced $\frac{3}{8}$ of an inch in one year. The voice changed in quality and speech became slow with difficult articulation. Moderate polyuria became evident but no polydipsia.

Physical examination: There was a great prominence of the supraorbital ridges with a receding forehead. The mandible and maxilla were greatly enlarged. The lips, nose, and ears were enlarged. The hands were large, broad, and spade-like. The skin was thick and coarse. The chest was barrel-shaped and scoliosis was present.

In 1937, x-ray therapy was instituted.

Subsequent Course: In March, 1939, he underwent a herniorrhaphy. This was complicated by a postoperative pneumococcal pneumonia. Recovery was satisfactory.

In January, 1940, he was in the hospital for four days with acute pharyngitis and acute bronchitis. Recovery was prolonged.

The patient has evidenced inadequate resistance to respiratory infection. This is secondary, I believe, to his acromegaly. It is often the case that the acromegalic succumbs to intercurrent infection.

completion of the second series of x-rays, shows a deposition of calcium in the sella, and the sella thereby somewhat narrowed. His symptoms were somewhat relieved by the treatments in three months following the second series. He has not lost any weight, is eating well, and feeling better at the present time. There has been no increase in his prognathism.

The second patient has been working all the time, except while receiving x-ray treatments. He states that he is feeling better, and that the symptoms have not increased since the treatment was started.

He also had a negative family history. He had had no previous serious illnesses and no operations.

In December, 1938, he noticed that his lower jaw seemed to be growing and that the dental ridges did not meet exactly. He complained of a general weakness and night sweats. He had a tinnitus, a slight deafness, and some vertigo. Because of his deafness, he consulted an eye, ear, nose and throat man who later referred him to a dentist.

On December 9, 1939, I saw him for the first time.

His blood pressure at that time was 120/70, the urine was negative, hemoglobin 82 per cent, red blood cells 4,200,000. His blood Wassermann test was negative. He also complained of a numbness of the fingers. Films were made of the skull with special reference to the sella turcica. There was enlargement of the sella, with evidence of erosion of the anterior half of the floor of the sella, findings indicating an enlarged pituitary gland. There was also a marked prominence of the frontal sinuses and supraorbital ridge with the entire skull also showing irregular thickening of the cranial table. The mandible was definitely enlarged and showed protrusion. The entire picture was character-

CLINICAL-PATHOLOGICAL CONFERENCE

istic of acromegaly with pituitary tumor. There was no evidence of increased intracranial pressure and there was no bitemporal hemianopsia.

The x-ray film of the third case illustrates again what destruction a pituitary tumor can cause to the sella turcica. This patient at the age of eleven was rather heavy-set with square shoulders. On x-ray at that time the findings, as illustrated on the slide, were present. He received two series of x-ray therapy and at the age of fourteen he had become slender, as compared with his former build, and had reached the height of six feet. This, apparently, was an eosinophilic adenoma which was on the way to producing gigantism.

Another case, of which I have no x-ray pictures, was that of a woman, forty-five years of age, who had al-

ways been rather heavy. She and her family noticed that there was suddenly a reduction in her weight, and that her voice became deep and masculine. Hirsutism developed over the face and body, and the thyroid became enlarged. She developed hypertension, glycosuria, polydipsia, and asthenia. Her basal rate was plus 45. Headache became a prominent symptom. In other words, she presented Cushing's syndrome, plus a hyperthyroidism. A diagnosis of basophilic adenoma of the pituitary gland was made, but the patient did not return for an x-ray of the skull. Arrhenoblastoma of the ovary was ruled out by pelvic examination, but a cortical tumor of the adrenal could not be ruled out. This case was possibly a case of adrenal tumor, but the headache and visual disturbance called attention definitely to the probability of a pituitary tumor.

CLINICAL-PATHOLOGICAL CONFERENCE

◆ MINNEAPOLIS GENERAL HOSPITAL ◆

Frank C. Andrus, Pathologist

CONSTRUCTIVE PERICARDITIS

Presentation of a Case

The case is that of a sixty-six-year-old white male who was admitted to the hospital on March 3, 1941, and who expired on December 2, 1941. He was first seen in June, 1939, when he had an irreducible indirect inguinal hernia on the right side. A herniotomy was performed. In addition, right orchidectomy was done since the testis was atrophic. His course was uneventful and he was discharged on the nineteenth postoperative day.

The patient's final admission to the hospital was on March 3, 1941. His presenting complaint was upper abdominal pain of three weeks' duration. The cardiac dulness was enlarged and the patient was thought to be in right and left heart failure. Rales were heard at the bases of the lungs. The liver was palpable. The venous pressure was 18 cm. of citrate. On the night of admission, the patient had auricular fibrillation. This was confirmed by an electrocardiographic tracing. The following morning, without specific therapy, normal sinus rhythm was restored and remained so until the time of death. Subsequently, he was digitalized and he responded well for about three weeks. However, at this time, a pericardial friction rub appeared. The venous pressure had dropped to normal and the dyspnea had disappeared. His blood pressure dropped from 110/80 to 96/60. It was felt that a pericardial effusion was present because of the configuration of the heart on percussion and the distant heart tones. This could not be demonstrated, however, either fluoroscopically or roentgenographically. An electrocardiographic tracing showed diminished

amplitude in all QRS complexes, which was thought to be consistent with pericardial effusion. The patient also developed the physical findings of right pleural effusion. A thoracentesis was done and 1800 c.c. of fluid were removed from the right chest. The fluid was a transudate in character and contained almost 100 per cent mononuclear cells. A few days later more fluid was removed and it then contained 78 per cent eosinophiles. The peripheral blood which had shown no eosinophilia began to have as high as 15 per cent eosinophiles. Prior to this period he had been running an elevated temperature but at no time was there a leukocytosis over 7,000. The sedimentation rate was never higher than 23 mm. per hour. The pleural fluid removed a week later revealed no eosinophils.

Several guinea pigs were inoculated with the pleural fluid but they were negative for tuberculosis. Several paraffin blocks of the sediment did not contain tumor cells. About one month after admission his temperature leveled off to normal; however, fluid continued to form in the right pleural cavity. It was necessary to remove between 1,500 and 2,000 c.c. of fluid at least twice a week. The venous pressure was consistently elevated and remained at about 15 or 20 cm. Mercurial diuretics produced profound diuresis but were ineffective in keeping down the pleural effusion. X-ray studies of the lungs were not satisfactory in so far as demonstrating any parenchymal pathology due to the pleural effusion and pleural thickening. A muscle biopsy revealed no evidence of trichinosis or periarteri-

tis nodosa. Bronchoscopic examination was negative. The urine showed 10 to 20 pus cells but was otherwise negative. Investigation of the genito-urinary tract showed normal intravenous and retrograde pyelograms. Cystoscopic examination revealed mild cystitis. At one time the patient had a mild, generalized lymphadenopathy. This subsided within a few days. The liver had been palpable two to three fingers below the costal margin throughout the hospital stay. A galactose liver function test was normal. Later x-rays of the chest were taken and revealed that the patient was probably developing a constrictive pericarditis. The patient began to run a septic temperature again in the fall of 1941 and began to get weaker and became emaciated. He developed ascites. His course was gradually downhill and he expired on December 2, 1941.

The patient was worked up extensively from a laboratory standpoint. Numerous guinea pig inoculations with sputum and pleural fluid were all negative. Numerous smears of the sputum were all negative. The blood urea nitrogen was normal. Studies of the blood were normal except for the time when the patient developed eosinophilia.

Clinical Diagnosis: Constrictive pericarditis.

Autopsy Findings: The body was that of a fairly well developed but emaciated white male weighing about 110 pounds. There was no edema or cyanosis. The lips and fingertips were cyanotic.

Upon opening the abdomen, the peritoneal surfaces were found to be covered with a brownish purulent exudate having a strong fecal odor. The peritoneal cavity contained 2000 c.c. of exudate. Many small white nodules measuring 5 mm. to 1 cm. in diameter were seen over the peritoneum, especially marked over the mesentery. The small and large bowel were matted together and were separated with difficulty. The right pleural cavity contained an estimated 1000 c.c. of reddish fluid and there were many fibrous adhesions over the lateral surface and the base. The pleura was markedly thickened and was adherent to the diaphragm. The left pleural cavity contained 100 c.c. of straw-colored fluid. Several enlarged lymph nodes varying in size from 2 to 3 cm. in diameter were found in the anterior-superior mediastinum which had caseous centers. The pericardial sac was obliterated. The pericardium was markedly thickened, its wall measuring at least 2 mm. in diameter. It surrounded the heart and constricted it.

The heart weighed 290 grams, the ascending aorta being included. It appeared rather small. The valves were normal. The coronary arteries were patent throughout.

The pericardium and pleura of the right lung were markedly adherent, there being one entire adherent mass in the lower right mediastinum. The lungs showed evidences of posterior hypostasis and consolidation; however, no pus could be seen in the bronchi. A number of small tubercles measuring 1 to 2 mm. in diameter were scattered throughout the right lung and a few were found in the left lung. A few white nodular areas were present in the right upper lobe which were undergoing caseous necrosis and had the appear-

ance of confluent miliary tubercles. A large thrombus was present in the artery to the left lung.

The spleen appeared normal grossly. The liver showed slight evidence of chronic passive congestion. The gall bladder appeared normal.

The intestines were matted together by adhesions. An ulcer could be seen in the jejunum which had perforated, the perforation measuring about $\frac{1}{2}$ cm. in diameter. There were several ulcers in the ileum measuring about 1.5 to 2 cm. which had raised borders and necrotic centers.

The pancreas and adrenal glands were normal grossly. The kidneys appeared normal. The bladder showed slight evidence of cystitis. The right testis was absent. The remainder of the organs were normal.

Smears were made from the mediastinal nodes and these were found to be teeming with acid-fast bacilli.

Anatomic Diagnoses: Constrictive pericarditis, generalized peritonitis, and miliary tuberculosis.

Discussion

DR. FRANK ANDRUS: Microscopic sections of the lymph nodes, intestine, lungs, spleen, and liver revealed the characteristic structure of tuberculosis. Judging from the size of the nodules, we are led to believe that those in the intestine were considerably older than the ones found elsewhere. We, therefore, believe that the disease started out as a tuberculous enteritis and peritonitis with a rupture of a tuberculous ulcer of the intestine giving rise to a generalized putrid peritonitis. Towards the latter part of the patient's illness, he was also developing a generalized miliary tuberculosis. At the time of death, the pericardium had completely healed so that we found only a dense covering of fibrous connective tissue containing only a few lymphocytes. There were no tubercles. We assume that the pericarditis was tuberculous in its origin but we are unable to prove it. We do not feel confident that we could exclude tuberculosis as a causative agent of the pleural effusion even in the absence of tubercle bacilli on the centrifuged sediment or from absence of lesions in guinea pigs inoculated with the fluid. We are unfamiliar with the cause of the eosinophilia except that it has been stated that this sometimes occurs when a pleural cavity is repeatedly tapped. Heart failure may have played a part in the production of this pleural effusion. The sections from the myocardium showed a mild myocarditis, not tuberculous. This may be due to the terminal sepsis with generalized peritonitis. We think that the thrombus in the pulmonary artery had its origin in an embolism. It was firmly attached at the time of death. In the absence of pulmonary congestion and hydrothorax on the left side, there was no infarction, as the lung was fed by the bronchial arteries.

DR. B. J. CLAWSON: I would like to comment upon the question of constricting pericarditis. The idea that the heart is firmly bound to adjacent structures by the fibrous pericardium does not put the condition in the category of constricted pericarditis. We have seen cases in which the pericardium was even calcified and the patient had never experienced any heart failure. I believe that we should regard constrictive pericarditis as a clinical but not a pathologic entity since I think that it is the constriction of the vena cava and the reduction of flow of blood to the heart that reduces the cardiac output. In other words, I think that the pump is good but it simply cannot get enough blood. Simple obliteration of the pericardial sac will not produce this.

PEDIATRIC-PATHOLOGIC CONFERENCE

DULUTH PEDIATRIC SOCIETY

O. W. Rowe, President

Arthur H. Wells, Pathologist

OSTEOMYELITIS OF FRONTAL BONE WITH RECOVERY

O. W. ROWE, M.D.

Duluth, Minnesota

D. C., a twelve-year-old boy, contracted a mild cold on September 1, 1940. His mother noticed that he blew his nose very hard and continued to do so. On October 7 he complained of headache over the right frontal area, and also some pain over the maxillary sinus area. He felt better on the next two days. On October 10 the pain over the frontal region and the sinus was extreme. He was taken to a physician in Rice Lake who advised tonsillectomy and adenoidectomy. On October 11 he complained of much more pain. He refused to blow his nose because of the pain, although he stated that it was stuffed up and breathing was difficult. Later in the day he had four convulsions, and was unconscious for most of the day. His temperature was 103.4°. On October 12 he felt somewhat better, was a little clearer mentally, and his temperature was down to 101°. On October 13 there was some congestion of the lungs noted by the local physician. He complained of pain in the chest and occasionally a mild cough, and perspired at times very freely. His temperature was 102.3°. The pain over the frontal and maxillary sinuses continued. He was then able to blow his nose but did not do so successfully. He entered the hospital late that day; temperature 104°, respiration 35, pulse ranging from 110 to 130.

He was a large, very well nourished male of twelve years. He was unresponsive and irrational at times. There was a swelling over the right frontal area which extended down to the right side of the face including the right eye, which was closed by the edema. The swelling extended about half way across the left frontal area and involved the left eye to a less extent. Crepitation was present. The left eyelid was swollen and painful to touch, and there was slight conjunctivitis. The right eye was closed and extremely painful. The eyeball itself seemed quite prominent and the lids could be separated. The pupils were equal in size. Rotation was diminished in the right eye, but there was no proptosis or external ophthalmoplegia. The fundi were normal. Examination of the ears was negative. The tonsils were enlarged and cryptic but not actively inflamed. There was postnasal discharge. The nasal septum was straight. There was drainage of pus-like material from the right nostril and the nasal mucous membrane was inflamed. He objected to movement of the neck but movements were not limited. There was good expansion of the chest. The heart was not enlarged and no murmurs were present. There was slight suppression of breath sounds on the left chest posteriorly but no rales or dullness was found. On the left side of the abdomen was a burn from a hot water bottle produced while patient was having convulsions. There was no paralysis or abnormal reflexes.

Lumbar puncture: Colorless, clear fluid, P.M.N.'s. 19, lymphocytes 48, R.B.C.'s. none; protein 20 m.g. per cent; chlorides 669 mg. per cent; sugar 85 per cent; pressure 18 mg. Hg. Blood: white blood cells 24,300; hemoglobin 81 per cent; red blood cells 4,030,000. Differential: nonsegmented 44, segmented 39, lymphocytes 11, monocytes 6. Urine: normal.

The diagnostic impressions in their order of importance were: sinusitis—probably ethmoiditis and extension to right frontal; encephalitis; poliomyelitis; meningitis; and possibility of cavernous sinus thrombosis. Treatment consisted of sulfapyridine 7 grains every four hours, hot packs, fluids, neosynephrine and argyrol, continuous steam. Later x-ray therapy to sinuses, blood transfusion, and saline and glucose hypodermoclysis were administered.

The following morning x-ray examination showed bronchitis with a small amount of parenchymal infiltration extending out from the left hilus. Sinus x-ray showed right maxillary and ethmoidal involvement with general slight pansinusitis. There was no evidence of bony destruction. There was a small collection of gas or air above the frontal sinus. On October 16 a blood culture, nose culture and throat culture all showed *Staphylococcus aureus*. The swelling over the frontal sinus began to feel much more doughy and a needle was inserted. About 15 c.c. of pus were obtained. Culture revealed *Staphylococcus aureus*. A transverse incision was then made and the remaining pus drained. The periosteum was elevated. On incision considerable pus was obtained from this. The lesion was packed with iodoform gauze. The patient became much clearer mentally. On October 17, the eyegrounds were still normal, he was mentally clouded but could be aroused. The temperature was somewhat lower. Sulfapyridine had been stopped and sulfathiazole, 7 grains every four hours, was given. Blood concentration was 6.4 mg. per cent. On October 18 another blood transfusion was given following which the white blood count dropped to 9,400. X-ray of the chest on October 15 showed no appreciable change. X-ray of the sinuses on October 28 showed pansinusitis, more marked in the right maxillary sinus. There was suggestive evidence of bony involvement in the left frontal sinus area.

The patient gradually improved, the swelling and tenderness decreased. He became clear mentally. The drainage from the incision and also from the nose continued but decreased in amount. His appetite improved. There was some diplopia which we believed would clear up. A small sequestrum was removed from this frontal bone on February 21, 1941, and the wound was packed with vaseline gauze. Recovery was eventually complete.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF THE MINNESOTA STATE MEDICAL SOCIETY

By ARTHUR S. HAMILTON, M.D.

Minneapolis, Minnesota

THE MINNESOTIAN of Saint Paul, July 16, 1853, contains the following note:

"We are requested to state that the medical profession of the territory will hold a convention at St. Paul, the 23rd instant."

So far as I am able to find any record, this represents the first attempt to hold a medical meeting in the district then known as Minnesota Territory. As there is no reference to this meeting in any of the subsequent transactions of the Minnesota State Medical Society, I must assume that it has escaped the attention of physicians and I shall, therefore, give the report literally as it appears in the public press.†

PROCEEDINGS OF THE MINNESOTA MEDICAL CONVENTION

Held in St. Paul, July 23, 1853

Pursuant to a previous notice through the newspapers and otherwise, a Convention of Physicians in Minnesota, met at the Court House in St. Paul, on July 23, 1853.

On motion of Dr. A. E. Ames, of Minneapolis, for a temporary organization, Dr. Thos. R. Potts, of St. Paul, was called to the chair, and Dr. Chas. L. Anderson, of St. Anthony Falls, was appointed Secretary.

On motion of Dr. Ames, it was

RESOLVED, That we, Physicians of Minnesota, deem it expedient to proceed to the organization of a Medical Society.

On motion it was also

RESOLVED, That the Convention resolve itself into a Committee of the Whole to produce a plan for the organization of a Medical Society in Minnesota.

PROCEEDINGS IN COMMITTEE OF THE WHOLE

Dr. John H. Murphy, of St. Anthony Falls, in the Chair.

Dr. Ames produced a form for the Constitution and By-Laws, made up largely from those in force in Pennsylvania and Illinois, which, after due consideration and amendment, was reported along with the National Medical Code of Ethics, to the Convention, and the Committee adjourned to meet in Convention at 2:00 o'clock p.m.

Afternoon Session

Convention met, and, on motion, the report of the Committee was unanimously adopted.

On motion of Dr. T. T. Mann of St. Paul, it was

RESOLVED, That medical gentlemen present, or recent residents, be invited to take seats and participate in the deliberations of this Convention.

Dr. Ames then moved that the Convention now resolve itself into the Minnesota Medical Society, which was passed.

On motion, a committee of three was appointed to nominate suitable officers and committees for the Society, to serve according to the Constitution and By-Laws for the ensuing year.

The President appointed Drs. Ames, Mann and Murphy to serve on that Committee.

After an absence of a few minutes, the report of the Committee was received, and the following gentlemen unanimously elected as officers for the ensuing year:

†*Northwestern Medical and Surgical Journal*, Chicago, 2:363, 1853. and *The St. Anthony Express*, III; No. 10, (July 30) 1853.

HISTORY OF MEDICINE IN MINNESOTA

President—Dr. Thomas R. Potts, of St. Paul.

Vice Presidents—Dr. John H. Murphy, of St. Anthony Falls, and Dr. A. E. Ames, of Minneapolis.

Corresponding Secretary—Dr. T. T. Mann, of St. Paul.

Recording Secretary—Dr. Chas. L. Anderson, of St. Anthony Falls.

Treasurer—Dr. J. D. Goodrich, of St. Paul.

Censors—Drs. Wm. W. Finch, J. H. Day and John J. Dewey, of St. Paul.

The following is the report on Committees, which was unanimously adopted:

Committee of Arrangements—Drs. Murphy, Anderson and Johnson, of St. Anthony Falls.

Committee on Practice of Medicine—Drs. Brisbane, of St. Paul; Carli, of Stillwater; and Anderson, of St. Anthony Falls.

Committee on Surgery—Drs. McDougal, of Fort Snelling; J. H. Day, of St. Paul; and Ames, of Minneapolis.

Committee on Obstetrics—Drs. Potts, of St. Paul; Murphy, of St. Anthony Falls; and Mann, of St. Paul.

Committee on Drugs and Medicines—Drs. Goodrich, Willey and Dewey, of St. Paul.

Committee on Publication (Ex-officio)—Drs. Mann, of St. Paul; Anderson, of St. Anthony Falls; and Goodrich, of St. Paul.

On motion, The Society then proceeded to ballot for a Delegate to the next meeting of the National Medical Association; which resulted in the election of Dr. John H. Murphy, of St. Anthony Falls.

Dr. Ames offered the following resolution:

RESOLVED, That this Society highly approve the efforts made by the National Medical Association to suppress the sale of intoxicating drugs and medicines. Unanimously adopted.

Dr. Anderson offered the following resolution, which was also unanimously adopted.

RESOLVED, That the next annual meeting of this Society be held at St. Anthony Falls.

On motion of Dr. Ames it was

RESOLVED, That the Corresponding Secretary be instructed to inform the National Medical Association of our willingness to coöperate with them.

The following Physicians were present and assisted in the organization of the Society:

Permanent Members.—Drs. Thos. R. Potts, James D. Goodrich, W. W. Finch, John J. Dewey, and T. T. Mann, of St. Paul; John H. Murphy, and Chas. L. Anderson, of St. Anthony Falls; A. E. Johnson, St. Anthony City; Alfred E. Ames, Hennepin County.

Present by Request.—Drs. A. W. Daniels, O. P. Marsh.

The following Physicians were not present, but had expressed a desire to coöperate with the Society and for that reason were unanimously elected members:

Drs. J. H. Day, A. G. Brisbane, and Samuel Willey, of St. Paul; McDougal, Fort Snelling; C. Carli, Stillwater.

After many expressions of hope for the success and usefulness of the Society, and the personnel of its members, it adjourned to meet again on the first Wednesday in June, 1854, at St. Anthony Falls.

C. L. ANDERSON and T. T. MANN, *Secretaries*

T. R. POTTS, *President*

I have been unable to find any record of the Constitution and By-Laws adopted on this occasion beyond the following paragraph which was introduced at the request of Dr. T. T. Mann, "from the record of another society," and which constituted the second article of the constitution.

The Objects of the Society

The objects of this Society shall be the advancement of medical knowledge, the elevation of professional character, the protection of the interests of its members, the extension of the bounds of medical science, and the protection of all measures adopted to the relief of suffering, and to improve the health and protect the lives of the community.*

The Constitution was printed and is listed in the catalogue of the Surgeon General's Library but cannot now be found.

There is no record that I can find of any meeting having been held in June,

*A committee, consisting of Drs. Hawley, Wharton and Kimball, was appointed at the February, 1869, meeting to revise the Constitution and By-Laws. Their report was adopted at the meeting of February 1, 1870, with no statement as to the preceding Constitution and By-Laws. There is, therefore, no means of determining how far the regulations adopted in 1870 are in keeping with those of 1853, but there is certainly no paragraph as accepted in the Constitution of 1870 which is in keeping with the paragraph mentioned above.

1854, as had been agreed upon, but *The Minnesota Republican* of January 17, 1856, under the heading "Minnesota Medical Society" says:

The following are the officers of this society for the coming year: President, Dr. Potts, St. Paul; Vice President, Dr. Murphy, St. Anthony; Corresponding Secretary, Dr. Goodrich, St. Paul; Recording Secretary, Dr. Wren, St. Paul; Treasurer, Dr. Day, St. Paul. Censors: Drs. Ames, Minneapolis; Smith, St. Paul; and Johnson, St. Anthony. Committee of Publication: Drs. Ewing and Marsh, St. Paul, and C. L. Anderson, Minneapolis.

Presumably a meeting of the society had been held just preceding this date but the newspaper for that particular week, most unhappily, is lacking in the State Historical Society files and no other note can be found up to Monday, February 1, 1869, when a meeting of the physicians of Minnesota was held at the International Hotel, in Saint Paul, "to consider the expediency of reviving the old society, or of organizing a new one." In the record of subsequent proceedings of this 1869 meeting, a short historical note gives the following: "In December, 1855, a Minnesota State Medical Society was organized, but no meetings had been held for several years previous to 1869."

In the further proceedings of the 1869 meeting, as reported in the lay press,[†] it is stated in respect to the meeting of 1855:

Two subsequent meetings were held, the last being at St. Anthony in 1857. After that period the society was allowed to languish. The rebellion broke out and a large number of members entered the service, and hence no meetings have been held, until the call appeared under which the society assembled today at 11:00 a.m., at the International Hotel.

Though at the meeting of February 1, 1869, it was accepted that a Minnesota* Medical Society had been organized in 1855, subsequent annual meetings, for some reason, have been dated as 1869. In reality, the date of actual founding was July 23, 1853, as is clearly shown by the *St. Anthony Express* of July 30, 1853. It is, moreover, almost certain that there was a meeting in 1856, but how many intervened between that of 1853 and the one of 1869 will probably never be determined.

At the 1869 meeting, the officers of the preceding session are given as:

President, Dr. T. R. Potts; Vice President, Dr. J. H. Murphy; Recording Secretary, Dr. J. V. Wren; Corresponding Secretary, Dr. J. D. Goodrich; Treasurer, Dr. David Day. Censors: Drs. W. H. Morton, F. R. Smith, J. H. Stewart, A. E. Johnson, and A. E. Ames.

As this list does not agree with the officers' names given in 1856, at must be assumed that a meeting was held between 1856 and 1869, but it so happens that the St. Paul city directory of 1856-57 gives the officers of the Medical Society of Minnesota exactly as appears above so that they must have been appointed at least as early as 1857. Furthermore, as Dr. Potts was obviously recognized in 1869 as the legitimate president and Dr. Murphy as the vice president, it must be assumed that the officers just mentioned are to be accepted as holding over from 1856 or about that date, and that no meeting between 1857 and 1869 had been held.

Since the regular transactions contain but a short account of the meeting of February 1, 1869, I will again make use of the lay report as it appears in the *St. Paul Pioneer Press*, with but little alteration:

[†]*St. Paul Pioneer Press*, February 3, 1869.

*It should be remembered that Minnesota as a Territory was not founded until March 3, 1849, and was admitted as a state May 11, 1858. Bearing these dates in mind will obviate the confusion which might otherwise arise owing to the rather loose use of the term "Minnesota State" in early days.

STATE MEDICAL SOCIETY

The Society assembled at 11:00 a.m., at the International Hotel.

Dr. Potts, the President of the Society, being absent, Dr. J. H. Murphy, the Vice President, called the assemblage to order, when Dr. D. W. Hand was elected Secretary.

A committee of three, consisting of Drs. J. H. Stewart, St. Paul, N. B. Hill, Minneapolis, and W. W. Mayo, of Rochester, was appointed on credentials.

The President, Dr. Potts, having entered the room, took the chair.

Dr. A. E. Ames, of Minneapolis, on behalf of the Censors, proposed the names of the following physicians as duly qualified for membership, and moved that they be elected, which motion prevailed:

E. J. Davis, J. C. Jones, Mankato; W. W. Mayo, E. W. Cross, Rochester; Hon. S. B. Sheardown, Winona; J. A. Allen, Austin; A. W. Daniels, St. Peter; O. Ayer, Le Sueur; N. B. Hill, C. G. Goodrich, Chas. A. McCollom, W. F. Hutchinson, J. J. [H. H.?] Kimball, J. H. Churchill, C. J. Dubois, H. A. Dubois, O. J. Evans, A. H. Lindley, Minneapolis; Samuel Willey, Alfrey Wharton, D. W. Hand, S. D. Flagg, Brewer Mattocks, Chas. E. Smith, E. H. Smith, A. G. Brisbane, John Steele, M. Hagen, J. B. Phillips, Adelard Guernon, St. Paul; W. A. Griffin, C. E. Rogers, Carver; W. W. Sweney, Charles Hewitt, Red Wing; A. C. Wedge, Albert Lea; J. C. Rhodes, H. F. Noyes, Stillwater; Solomon Blood, Owatonna.

The committee on credentials reported the above list, together with the officers of the Society, as entitled to seats in the convention, which report was adopted.

Some time was spent in desultory discussion concerning the revival of the old Society or the organization of a new one, when, by unanimous consent, it was resolved to reorganize.

The Society being thus resolved into a general convention, the same temporary officers were elected chairman and secretary.

Dr. Ames moved to proceed to the organization of a new society.

Dr. Hewitt, of Red Wing, was opposed to such hasty action. He favored the appointment of a committee to propose a constitution and bylaws, which committee could report at some subsequent meeting in the fall, thus giving the different counties and districts throughout the State time to organize auxiliary societies and send regular delegates to the adjourned State Convention.

Several other gentlemen took part in the discussion, which was cut short by Dr. Stewart moving the appointment of a committee of five to report a constitution and bylaws for a permanent organization, which motion prevailed.

The chair appointed Drs. J. H. Stewart, of St. Paul; A. E. Ames, Minneapolis; W. W. Mayo, Rochester; A. C. Wedge, Albert Lea; and Charles Hewitt of Red Wing, as such committee.

The committee retired, and, on returning, the majority report was in favor of the adoption of the old constitution and bylaws for the government of the new Society, changing the time of the annual meeting to the first Tuesday in February.

Dr. Hewitt made a minority report, again favoring a postponement until fall. The majority report was adopted.

On motion of Dr. Murphy, the chair appointed a committee of five, consisting of Drs. Wharton, Stewart, Ayer, Kimball, and Dubois, to nominate officers for the ensuing year.

After retiring to deliberate, Dr. Wharton, from said committee, submitted the following report:

President—Samuel Willey, St. Paul.

Vice President—A. E. Ames, Minneapolis.

Corresponding Secretary—Alfred Wharton, St. Paul.

Recording Secretary—E. J. Davis, Mankato.

Treasurer—Hon. S. B. Sheardown, Winona.

Censors—J. H. Murphy, St. Paul; N. B. Hill, Minneapolis; W. W. Mayo, Rochester; A. C. Wedge, Albert Lea; J. C. Rhodes, Stillwater.

Standing Committee—A. G. Brisbane, St. Paul; E. C. Roger, Carver; J. E. Finch, Hastings.

The Convention then took a recess until 2:30 p.m.

Afternoon Session

On re-assembling Dr. Samuel Willey, the President-elect, assumed the chair, and briefly thanked the Society for the honor conferred upon him.

Dr. Ames moved the appointment of a committee of three, as the organ of the Society, in reference to Legislative enactments, affecting the organization throughout the State.

This motion provoked considerable discussion, participated in by Drs. Hewitt, Potts, Goodrich, Blood, Sheardown, Noyes, Mayo, and others, and finally culminated in the adoption of the following resolution, offered by Dr. Day of St. Paul:

HISTORY OF MEDICINE IN MINNESOTA

RESOLVED, By the State Medical Society assembled, that in case the Legislature now assembled desire to protect the citizens of this State against quackery, it is the duty of this Society to coöperate with the Legislature, and lend its assistance in framing all needful laws upon the subject; and that Drs. Willey, Sheardown and Stewart be appointed a committee as the organ of the Society for this purpose.

On motion of Dr. Ames, the President appointed Drs. Murphy, Hewitt, and Sheardown delegates to the American Medical Association which meets in New Orleans the first of May next.

Dr. Hewitt offered the following resolution which was adopted:

RESOLVED, That we urge upon members of the profession throughout the State to perfect local organizations as provided by the regulations of this Society, not only as materially assisting to sustain it in a state of greater efficiency, but to perfect local as well as the State organization, and to increase that feeling of lively interest in the profession so essential to its prosperity and success.

The convention then took a recess until 7:30 P. M.

Evening Session

Convention met at 7:30 P. M., Dr. Murphy in the chair.

Dr. Blood, of Owatonna, moved that a committee of three be appointed to revise the constitution and bylaws and report at the next annual meeting. Carried.

The chair appointed Drs. Hawley, Kimball and Wharton such committee.

On motion of Dr. Mayo, the chair appointed Drs. Mayo, Blood and Phillips a committee on finance.

It was decided that an assessment of \$2.00 upon each member would meet the necessary expense.

Dr. Hewitt moved that the Society hold semiannual meetings, in different localities throughout the State, and that the first meeting be held on the 17th of June next, which motion prevailed, and Owatonna was selected as the place of meeting.

The Vice President of the Society was appointed to deliver an address upon that occasion, and Dr. Kimball to read an essay. Dr. Hewitt, of Red Wing, was appointed to deliver the annual address before the Society.

Drs. Hewitt, Noyes and Sheardown, having been appointed a committee to draft a program for the meeting at Owatonna, reported the following order of exercises:

- (1) Essay by Dr. Kimball; Subject, Rheumatism.
 - (2) Dr. Wharton of St. Paul, and Dr. A. B. Stuart of Winona, to introduce the discussion of the Essay.
 - (3) Discussion on Quackery; Its Diagnosis and Treatment. Drs. Mattocks and Hewitt to open the discussion.
 - (4) Adjourn until 7:00 P. M., when the address of the Vice President will be delivered, with general discussion of the subjects suggested in the address.
 - (5) Report of Committees. Adjournment.
- The report was adopted.

Dr. Blood moved that each member of this Society be requested to report some case in his own practice at each meeting for discussion. Adopted.

Dr. Blood also offered the following resolution, which was adopted:

RESOLVED, That a committee of one from each county be appointed to report the names and number of practicing physicians in their respective counties; also, the number practicing in their counties who are not recognized as physicians by this Society, and their classification.

The chair appointed Drs. Brewer Mattocks, of Ramsey; W. W. Sweney, of Goodhue; H. F. Noyes, of Washington; W. A. Griffin, of Carver; A. C. Wedge, Freeborn; E. J. Davis, of Blue Earth; W. W. Mayo, of Olmsted; S. B. Sheardown, of Winona; and N. B. Hill, of Hennepin, as such committee.

On motion of Dr. Sheardown, a vote of thanks was unanimously tendered Col. E. C. Belote, of the International Hotel, for the use of the room and the attention and courtesies shown the Society at this meeting.

After some desultory conversation upon minor topics, the Convention adjourned to meet at Owatonna on the 17th of June next.

First Semiannual Meeting

The first semiannual meeting of the Society was held at Owatonna, June^o 16, 1869, at Dresser's Hall. The Society convened at 11:00 a.m., and, in the absence of both presiding officers, Dr. J. H. Murphy was chosen temporary chairman.

The minutes of the last meeting were read and approved.

The members present were: Drs. Mayo, Murphy, Mattocks, E. H. Smith, Lindley, Hutchinson, Blood, Sheardown, Noyes, Rhodes and Davis.

On motion, the following committee on credentials was appointed: Drs. Noyes, Lindley and Mattocks.

The Society then adjourned to meet at 2:00 p.m.

Afternoon Session

At 2:00 p.m., the committee on credentials reported the names of the following physicians, as qualified for membership, and on motion they were elected:

Drs. F. S. Bodle and S. L. Bennett, Owatonna; F. H. Milligan and W. L. Lincoln, Wabasha; W. H. H. Richardson and J. B. McGaughey, Winona; E. S. Gibbs, Geneva; C. Hill, Pine Island; L. Redmon, Preston; H. H. Guthrie, St. Charles; O. W. Sadler, Concord; C. P. Adams, Hastings; J. B. LeBlond, Brownsville; F. M. Rose, Faribault; J. L. Wakefield, Shakopee; E. C. Cross, Rochester; C. H. Boardman, St. Paul.

In the absence of Dr. Kimball, his essay on "Rheumatism" was read by Dr. W. F. Hutchinson.†

Dr. Willey, having arrived, took the chair.

The committee appointed to ascertain the number of regular and irregular practitioners in the state, presented the following report:

	Regular	Irregular
Ramsey	24	21
Hennepin	18	21
Washington	4	5
Fillmore	11	8
Dakota	5	4
Houston	4	5
Wabasha	8	4
Steele	5	4
Olmsted	8	6
Goodhue	8	4
Winona	20	9
Dodge	4	2

Dr. Rhodes, of Stillwater, introduced a motion prohibiting the admission of any person to membership in the Society who could not produce satisfactory evidence of being a legal practitioner of medicine. After considerable discussion by the members the resolution was adopted, though it must have led to serious misgivings in the minds of more than one present.

The Society then adjourned to meet at 8.00 p.m.

Evening Session

The Society again convened; Dr. Murphy in the chair.

Dr. Murphy announced that the president, Dr. Willey, offered for competition by members of the Society, the two following prizes: \$50.00 for the best essay on the "Epidemic and Endemic Diseases of Minnesota"; and \$50.00 for the best essay on "Cerebro-Spinal Meningitis"; the relative merits of the essays to be determined by committees to be appointed by the President, and the names of the successful competitors not to be made known until after the awarding of the

†So far as the records show, this is the first scientific contribution to the Society.

prizes. The thanks of the Society were tendered to the President for his liberality.

Dr. Mattocks, of Saint Paul, then opened the discussion on "Quackery," and as might have been expected, with Mattocks' ready tongue, a lively debate ensued. Drs. Rhodes, Sheardown, Blood, Hutchinson, and others were participants. Finally, to reestablish peace, as we may assume, the subject for discussion was changed to the less personal one of typhoid fever. Here again disagreement probably developed and the debate was ended by the appointment of Drs. Milligan, Hill and Richardson as a committee to report upon the origin, nature and treatment of typhoid fever, at the next meeting.

After the adoption of votes of thanks to the presiding officers of the meeting, and to the citizens of Owatonna, and particularly to Dr. Blood, for his hospitality, the Society adjourned.

Annual Meeting

Beginning with the annual meeting at Saint Paul, February 1, 1870, the records of the meetings are very complete, and are so widely distributed that no attempt will be made to give even an abstract of all the transactions, and only those matters that at the time seemed important, or later became so by virtue of subsequent happenings, will be referred to.

Previous to this date, references in the public press to medical men and their interests were neither frequent nor full and often not friendly. The new country was full of newspapers, many of which were ephemeral and the editors often attacked each other with a vigor and viciousness that might well have reconciled the doctors to a place more or less out of the limelight.

Moreover, Minnesota was settled at a time when questions of very grave national interest were agitating the public. The difficulties between the North and the South and the matter of slavery, the Kansas Free Soil agitation, and the subsequent Civil War, the Indian and the Mormon troubles, absorbed the attention of editors and their readers alike to a large degree, and what time was left from these more or less national questions was largely devoted to a consideration of the growth and extension of population and of railroads, to the subduing of the wilderness that extended in every direction, and to the question of local religious and political activities, which latter were often discussed in a manner more animated than dignified.

(To be continued in the February issue.)

CHOLERA POSSIBLE IN JAPAN IF CROWDED CITIES ARE BOMBED

Effective bombing of Japan's crowded, inflammable cities might easily give rise to an epidemic of the deadly Asiatic cholera, U. S. Public Health Service epidemiologists believe.

Two cases of cholera in at least one Japanese province (Taiwan) have been reported to the Public Health Service this year, and it is believed many more occurred. Cholera prevails in the Far East but there is none in the United States.

Cholera is spread by eating raw foodstuffs and drinking water infected with the microscopic curved rods which are the cholera germs. Normal supervision of these sources would be disrupted by severe bombings of Japanese "paper" cities.

A far higher number of people would be made homeless in Japan by bombings than in this country where living quarters are less crowded and more durable.—*Science News Letter*, January 3, 1942.

H. Z. GIFFIN, M.D., President,
Minnesota State Medical Association

President's Letter

IN his December letter Dr. B. J. Branton "passes the torch" to his successor. You will, I am sure, desire me to record here the facts you know so well—that he has in an exceptional manner performed the work of the presidency, that he has traveled often and far to discuss pertinent questions with members of the association and by his personality to promote loyalty and professional integrity, and, most important of all, that he has done more than his share to accomplish coöperation and kindness within the profession and between the various professional groups of the state.

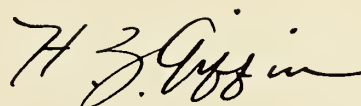

It is a great honor you have bestowed upon me and I appreciate it highly. It carries with it a great responsibility. As a member of the Council for more than eight years I have become somewhat familiar with the problems of the Association. Acting as President, however, is a duty like no other and I must learn from my predecessors. There is, to be sure, an element of sadness in the thought that I shall be gradually retired from active participation in the affairs of the Council and from association with men of such unselfish judgment and loyalty. My chief aim during the year shall be to carry the messages of the House of Delegates and the Council to the membership and those of the members to the officers.

This is our first year of war. It will be a difficult year for the State Association—a year for both vision and action. We must provide not only physicians for service with the armed forces but also adequate medical care at home with reduced personnel. Coöperation, coördination and expansion are the watch words: coöperation with existing agencies, coördination with governmental services, expansion of certain activities important to education, public health and civilian defense.

Each member of the Association is a unit of importance, but specific accomplishment can be attained best through the work of our committees and our administrative staff. So I say let us support our committees in their work. The members of these committees give time and effort gratis and they should not be allowed to become discouraged. In January, conditions permitting, I propose to call a meeting of the chairmen of scientific committees so that a sympathetic understanding of the province and program of the work of each committee may be had by all, with respect to war work and civilian defense and also with respect to long term activities.

Specific problems cannot be discussed in detail in this letter but two subjects should be mentioned concerning which every physician should be well informed at this time: Civilian Defense and the Service of Procurement and Assignment of Physicians. In this connection I suggest that we read regularly not only our news letter and the section on Medical Economics of MINNESOTA MEDICINE but also, and by all means, the section on Medical Preparedness in the *Journal of the American Medical Association*. Developments along these lines will be not only important but interesting.

In all our war work, however, we should not forget the basic reason for being a doctor—the care of the patient. For this we must be well informed and to be well informed we must take advantage of every means to further our own knowledge of medicine—extension services, continuation study, postgraduate assemblies and clinic weeks, as well as meetings of our medical societies. We should take advantage of our best investment—an ever growing knowledge of the science and art of medicine.

PHYSICAL DEFECTS OF SELECTEES

WITH the increased need in the national
emergency for more men, consideration of
the nature and extent of disqualifying physical
defects challenges the interest of every physician.
Col. Hullsiek² reported in May, 1941, that ap-
proximately 1,000 members of the medical and
dental professions examined over 35,000 regis-
trants in the State of Minnesota and found 64
per cent of these fit for general military service,
13 per cent fit for limited military service and
23 per cent unfit for any military service. Insuf-
ficient teeth accounted for 29 per cent of dis-
qualification compared to 3.1 per cent in 1917-18.

The author of the above report was unable to
state whether this variation represented a change
in dental condition or of more rigid application
of standards at the present time. It appears prob-
able that the divergence is due to more rigid ap-
plication of standards. Cardio-vascular, musculo-
skeletal, eye and nervous and mental disqualifica-
tions varied from 13.1 to 10.3 per cent. Tuber-
culosis as evidenced by total respiratory disease
was infrequent and there were only 76 (0.2 per
cent) new cases of syphilis encountered in 30,333
men. A report from the state headquarters of the
Selective Service System dated September 19,
1941, shows that of 152,289 registrants from Min-
nesota classified to date, 21,223 have been in-
ducted or are available for military service and
that 15,330 were physically, mentally or morally
disqualified. The group of miscellaneous, agri-
cultural, industrial and defense deferments were
25,739 with dependency leading all other causes
at 81,457.

It is self-evident that preventable infectious
diseases were of infrequent occurrence and that
insufficient teeth to meet the standards was the
chief disqualifying defect. The correction of den-
tal defects in men otherwise physically fit presents
a problem that might well be met by the indi-
vidual and his dentist. With indignity, special
measures appear necessary and in other instances
continued adjustment in fees according to the in-
dividual's ability to pay. The Selective Service
proposed¹ that minor defects, chiefly dental, be
corrected by sending the men to local physicians
and dentists through the authority of the local
boards with fees to be paid by the United States.
It is understood that this is an emergency meas-
ure. With the demands that will now be made
upon the medical profession for the proper ex-
amination of registrants and medical care in dif-
ferent branches of the armed forces and in the
civilian population it is to be doubted that diver-
sion of even a small number of physicians for
correction of minor surgical defects will be found
feasible. Under usual circumstances the correc-
tion of defects would be limited to those who
would choose to have a recommended procedure
under a surgeon of their choice and this method

should continue to be operative for those few who would so elect. General Hershey² stated that the army would be asked to induct on a waiver those individuals who refused to have a corrective procedure which would lead to qualification.

Although at first sight the number of physically defective individuals seems large it is gratifying to note that the incidence of preventible infectious diseases is low. The high incidence of individuals who have not had restorative dentistry speaks for lack of health education and lack of appreciation of present facilities for care rather than any limitation of those facilities. When the present emergency shall have ended in victory through the coöperation of all, a campaign of health education, leading to a better appreciation in the public of the facilities for medical practice, of the value of vaccination and other preventive measures, of tuberculosis and venereal disease control, of oral hygiene and of nutrition and of periodic physical examinations, may well be led again by the medical profession with its allies in Public Health Administration and Education. Incidentally the many hours of service rendered by the volunteer physicians for the local boards is to be commended as an expression of patriotism consistent with best professional ideals. In this way also American medical practice has made good.

WORLD WAR II

WITH the beginning of the year we face a threat to our national security as great as we have ever had. For the first time in our history our country has been attacked and we have been forced to fight, not one country, but a combination of three totalitarian powers of known and unknown military and naval power. The treacherous initial attack by Japan before any declaration of war, caused great damage, but proves the tactics of the Japanese are true to the German form.

Whereas there has been until now some question in certain quarters as to the existence of an emergency, as to the need for emergency measures in our defense program, and as to the dan-

ger of invasion from across the sea, these questions were dramatically answered on December 7. Possibly the stunning effect of the surprise attack was a blessing in disguise. Certainly the result has been a sudden unification of the elements in our population.

We predicted in an editorial just a year ago that we would have to decide in the near future whether we would prefer to meet this foreign combination of nations at some future date, possibly alone, or at an earlier date in alliance with a powerful empire. It has been decided for us. We are fortunate in having an additional powerful ally in Russia, even though we may heartily disapprove of the Russian form of government.

The time for discussion of national policy is gone. It is the duty of every citizen to do his bit in the defense of his country. The demand for doctors will be even greater than it has been. An economy of doctors' hours will have to be practiced. The plans contemplated by the Selective Service in the selection of draftees will be saving in this respect. The delegation of routine administrative matters in the army to other than those medically trained deserves consideration.

The various armed services will need many more doctors. The production of new doctors cannot be speeded up very much. What can be done by the elimination of medical school vacations should be done. The enrolled medical students are not being drafted until the completion of their internship. Internship in some military general hospitals is as valuable as in certain civilian hospitals and substitution might be possible.

War today is proving to be more and more a war of aviation. Navies without the protection afforded by airplane fighters are helpless. Control of the air is fully as important for armies. This will result in a great impetus to aviation medicine.

The medical profession of America has never been lacking in patriotism. We shall not fail in World War II.

A report from Moscow says that, preparing for *winter fighting*, soldiers in the Moscow area have practiced marching on skis over rough terrain, tossing grenades and shooting from various positions on skis; and first aid detachments on skis have been organized. —*Science News Letter*, December 20, 1941

**ENROLLMENT FORM FOR PROCUREMENT AND
ASSIGNMENT SERVICE FOR PHYSICIANS**

Dr. Sam F. Seeley, Executive Officer
Procurement and Assignment Service
New Social Security Building
4th and C Streets S. W.
Washington, D. C.

Dear Doctor Seeley:

Please enroll my name as a physician ready to give service in the Army or Navy of the United States when needed in the current emergency. I will apply to the Corps Area commander in my area when notified by your office of the desirability of such application.

Signed.....

1. Give your name in full, including your full middle name:
.....
2. The date of your birth:
.....
3. The place of your birth:
.....
4. Are you married or single?
.....
5. Have you any children? If so, how many?
.....
6. Do you believe yourself to be physically fit and able to meet the physical standards for the Army and Navy Medical Corps?
.....
7. Have you filled out previously the questionnaire sent to all physicians by the American Medical Association?
.....
8. When and where were you graduated in medicine?
.....
9. In what state are you licensed to practice?
.....
10. Do you now hold any position which might be considered essential to the maintenance of the civilian medical needs of your community? If so, state these appointments:
.....
.....
11. Have you previously applied for entry into the Army or Navy Medical Service? If so, state when, where and with what result (if rejected, state why).
.....

Signature.....

Date..... Address

ENROLL NOW!

UNCLE SAM needs more physicians for the military services. The amendment to the Selective Service Act makes all men under forty-five years of age, physicians included, subject to service.

In order that the service of a considerable proportion of the physicians in the army will not cause any greater inconvenience to civilian communities, public health agencies, and industrial plants than necessary, the Procurement and Assignment Service for Physicians and Veterinarians was established by the President on October 30.

At a joint meeting of this committee with the Committees on Medical Preparedness of the American Medical Association, the American Dental Association, and the American Veterinary Medical Association, plans were made for obtaining the names of physicians who wish to enroll promptly in the service.

In *The Journal of the American Medical Association* for December 27 appeared a blank, reproduced herewith, which should be filled out and mailed to Dr. Sam F. Seeley at Washington by those physicians under the draft age of forty-five who consider themselves physically fit and not essential for civilian needs in their communities. This should assure their assignment to the type of service for which they are best fitted. This will also avoid the possibility of unclassified service in the army. A physician called by the Selective Service who has not enrolled or who is not on a reserve list, obviously serves without a commission during the time that necessarily elapses before a commission is secured.

**CURE FOR ATHLETE'S FOOT
DISCOVERED BY SCIENTIST**

A cure for athlete's foot which stops itching immediately and leaves no stain on skin or clothing is announced by Dr. Edward Francis, medical director (retired) of the U. S. Public Health Service. (*Journal, American Medical Association*, Dec. 6.)

Dr. Francis' remedy consists of a mixture of three parts phenol and one part camphor which can be prepared by any pharmacist. He reports that the mixture is "nonirritating and may be painted between the toes several times a day. The sock may be replaced immediately without danger of corrosion."

Users are warned, however, that the preparation should not be applied to wet skin.—*Science News Letter*, December 13, 1941

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association
George Earl, M.D., Chairman

PHYSICIANS ARE READY

The impact of war found the Minnesota State Medical Association with machinery already functioning to deal effectively with problems of increased personnel for the armed forces and of redistribution to fill in gaps left by men called to active duty.

The Council of the Association, meeting one week after the attack on Pearl Harbor, went on record offering its services in aid of the newly organized Procurement and Assignment Service for Physicians, Dentists and Veterinarians to the end that a sufficient number of qualified medical men may be secured for the armed forces without, at the same time, stripping the civilian population in Minnesota of needed medical service.

In Civilian Defense

Full coöperation with the Office of Civilian Defense in organization of Emergency Medical Field Units was pledged also and members were urged to volunteer for this service in their home communities, as soon as local plans are worked out.

The importance of civilian health in time of war was likewise recognized and all organized facilities of the Association will be utilized, especially, to extend public knowledge of nutrition and to push to the utmost campaigns of vaccination and immunization in the population.

For Better Nutrition

Plans for publication of simple diet sheets for children, for normal and overweight adults, and for pregnant mothers were outlined and approved. These sheets will be prepared by nutrition authorities. They will be distributed without charge through the doctors of the state.

Attractive posters exhibiting a family group with the query, "Is Your Family Protected

Against Smallpox?" have already been prepared and sent to every member and to public health nurses and school superintendents all over the state. With the poster went a printer's proof of a leaflet "stuffer" with the same picture and a somewhat extended message for use with statements and for distribution at meetings and schools. Both the poster and the stuffer are available in quantity without charge from the state office. They will be distributed as widely as possible at the direction of the Council during the coming year.

To Control Communicable Disease

Health authorities know that communicable disease is a bigger defense problem than injuries from battle, even among the armed forces. Among civilians every effort is needed to hold down days lost from sickness and there will be no excuse if a malignant epidemic of smallpox is allowed to work tragic and unnecessary havoc with the defense effort in Minnesota.

Physicians of Minnesota have always been ready to answer the call to arms of their country, in every branch of the selection and training of the armed forces and in the care of the wounded on the battle front. In this war more than ever before, they are extending their responsibilities as an organization to the protection of civilian health and effectiveness in the emergency.

THE PUBLIC HEALTH SERVICE LOOKS AT FREEBORN COUNTY

The report just issued by Surgeon Dean Clark of the United States Public Health Service on the medical care program of the Welfare Board of Freeborn County is of extraordinary interest to anyone who has watched Minnesota's system of medical care for recipients of relief and social security aids take shape over the last ten years.

In Freeborn County, most of the features regarded by physicians as essential to any plan

for care of the needy sick have been incorporated into the welfare policy of the county and have proved themselves to be economically sound. If all are not yet developed to the fullest expectation of the planners or to the complete satisfaction of the public health service investigator, at least an unusually satisfactory groundwork has been laid. Improvements can be made as they are needed without disturbing the general structure.

Free Choice for Patients

There is free choice of physician for all recipients of relief or social security aids in Freeborn County. This highly desirable state of affairs was established in 1938 after a long and unhappy experience with the county doctor system. Objection to free choice had previously been a matter of cost and it is to the credit of the physicians of the county that they took the initiative to abolish the county doctor system. They agreed to do the work on a prorata basis with free choice to the patient for an amount which should not exceed the funds allocated for the purpose under the county doctor plan.

It is even more to their credit that, in so doing, their medical advisory committee has established such close working relations with the county welfare board that the result is a matter of special commendation in the report of Surgeon Clark.

Praise for Doctors

Praise for this vigorous coöperation and also for the conscientiousness and effectiveness of the committee in auditing monthly bills of physicians is voiced several times in the Clark report and should be called to the attention of those who have always been skeptical of the ability of physicians' committees to regulate and discipline their own members.

Freeborn County doctors are still paid for their work on a fee basis, within the limits of a definite fund set aside by the county welfare board to cover medical services and drugs. For the year 1940 that fund amounted to \$8,500. Fees were paid according to a fee schedule which was, in many categories, considerably lower than the schedule of allowances just adopted by the Division of Social Security in consultation with the State Medical Advisory Committee and about to be recommended by Mr. Walter Finke, director, for use of welfare boards.

It is interesting to note that in terms of per

capita amounts the physicians received \$2.53 per eligible person receiving old age assistance and \$3.74 per eligible person receiving direct relief.

Is Compensation Reasonable?

On the question of whether or not this amount represents reasonable compensation to the physicians who rendered the care, Surgeon Clark makes the following observation, in his report:

"One way of getting at the answer is to find out what the average income of physicians would be if in private practice they received an amount per person in the population equivalent to their welfare income. If every person under the age of sixty-five in the county were to pay his physician an amount equal to that paid during the study year to physicians per direct relief recipient (\$3.74), the total would come to \$11,780. If to this sum were added, for every person in the country aged sixty-five or over, an amount equal to that paid per recipient of old age assistance (\$2.53), the total would be \$116,560—an average of \$4,857 each for the twenty-four physicians in active practice in the country."

The further observation made by this commentator that, on this basis, the physicians are adequately paid for their work is open to many objections. Chief among them is the fact that overhead consumes so heavy a percentage of the physician's income. The percentage runs from 25 to 50 per cent, depending upon the size and standards of the community. Assuming that Freeborn County physicians must pay an average of the median between these two, their net income on the basis arrived at by Surgeon Clark would be approximately \$3,000 a year, which is obviously far from an adequate return. Also there is the fact that many residents of all counties do not seek medical care even when they are able to pay for it and there are others who receive it as charity and are never on relief or public assistance rolls. It is extremely doubtful if the average level of gross income for the physicians of the county, even with payments made to them by the county welfare board, reaches anything approaching the estimated average.

Provision for "Medically Needy"

Other sound policies established in Freeborn County include hospitalization for a large number of recipients in the local hospital at Albert Lea; provision for medical care of the so-called "med-

ically needy," borderline cases who are not eligible for direct relief or social security aids but who cannot take care of medical and hospital bills; and vaccination and immunization for all recipients of relief and aids.

Surgeon Clark feels that the care of the medically needy is far less complete and satisfactory than the care provided for recipients of direct relief; that policies of the board for these people should be expanded and that such an expansion would be economically sound. He believes also that facilities for hospitalization within the county need expansion and that the policy with regard to handling of obstetrics should be altered to put more emphasis on prenatal care. Other recommendations have largely to do with centralization of responsibility within the welfare board and elimination of some authorization red tape between the patient and the physician.

The striking thing to anyone who knows the difficulties that have attended organization of medical relief everywhere is that nearly all of the things for which physicians have struggled for many years are completely conceded in principle here in this typical Minnesota farming community and that most of them are working out with satisfaction in practice, as they are now in most other counties of the state. Improvements will come with experience and the recommendations made by Surgeon Clark may be of assistance in hastening them. The fact remains, however, that the plan which the doctors of the county conceived and put into effect and which they are actively and unselfishly engaged in carrying forward in Freeborn County has proved its worth. The county doctor is receding rapidly from the relief picture in Minnesota.

SUGGESTED ALLOWANCE

Final copies of the schedule, prepared by the Division of Social Security, of suggested allowances for medical service to recipients of relief and public assistance were presented for inspection of the Council at the December meeting. They will be in the hands of all county welfare boards and medical advisory committees in the state by the time this issue goes to press. Additional copies will be mimeographed in the State Office and sent to members outside the large cities at an early date.

This new schedule supersedes the fee schedule

of 1937 which has been in rather general use throughout the state. It was drawn up at the direction of Mr. Walter Finke, director of the Division of Social Welfare, following an intensive study of the problem of uniform fees in rural areas by the medical unit of the division. The state-wide medical advisory committee coöperated in this study and it had the benefit of information about usual charges gathered independently by a committee of the Council from sixteen component societies representing sixty of the eighty-four rural counties of the state.

In contrast to the 1937 schedule, this new table of allowances provides in general for a reduction of $33\frac{1}{3}$ per cent instead of 40 per cent from usual fees.

The list includes 211 types of services commonly given by general practitioners. It was presented in tentative form to the Council at an earlier meeting and recognized by that body as reasonable. It is, of course, not designed for use in cities of the first class inasmuch as the law requires use of existing philanthropic agencies for the needy in the metropolitan areas.

It should be emphasized in connection with the distribution of this schedule that the county welfare boards are actually the responsible authorities in all matters of allowances and payments. The new schedule will be recommended for use but cannot be enforced under the law by the state agency.

In most parts of the state, however, recommendations from the Division of Social Welfare are taken into account, at least, and also successful working relations have been established between the county boards and local medical advisory committees.

Allowances to be paid in any specific county will necessarily be determined by the boards and committees who know the problem best and in view of local budgets and needs.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

J. F. Du Bois, M.D., Secretary

Saint Paul Chiropractor Given Four-year Prison Term
Re: State of Minnesota vs. Edward Ferdinand Jacobson

On December 9, 1941, Edward Ferdinand Jacobson, sixty-one years of age, entered a plea of guilty in the District Court of Ramsey County, Minnesota, to an information charging him with the crime of abortion.

Jacobson, who holds a license to practice chiropractic in the State of Minnesota, and who had an office at 244 Hamm Building, Saint Paul, Minnesota, was sentenced to a term of not to exceed four years in the State Prison at Stillwater, by the Hon. Albin S. Pearson, Judge of the District Court. The defendant offered to surrender his basic science certificate and chiropractic license if the Court would suspend the sentence and place him on probation. Judge Pearson told the defendant that the Court could not show him any leniency because he had a previous conviction of practicing medicine without a license that grew out of a similar case.

Jacobson was arrested on November 28, 1941, by the Saint Paul Police Department following the admission of a twenty-one-year-old Saint Paul girl to Ancker Hospital for treatment following a criminal abortion. The girl made a statement involving Jacobson and he was immediately arrested. The girl stated that she had paid Jacobson \$6.50 for his services. On December 1, 1941, Jacobson was taken to Ancker Hospital for a mental observation, but the examining physicians concluded that he was sane, and on December 6, 1941, a complaint was filed against him charging him with the crime of abortion. Jacobson was arraigned in the Municipal Court in Saint Paul, on December 8, 1941, where he waived a preliminary hearing, and was held to the District Court. On December 9, 1941, he entered a plea of guilty to an information charging him with the crime of abortion and was sentenced as reported above.

Jacobson told the Court that for thirty years he had been an employe of the Railway Mail Service, but retired in 1940 on pension. Jacobson admitted that on November 1, 1940, he had pleaded guilty in the District Court of Ramsey County, to an information charging him with the crime of practicing medicine without a license. Jacobson paid a fine of \$200.00 at that time. Jacobson cannot be heard to complain that he was not properly warned in 1940, for at that time, Judge Loevinger told him: "Should you attempt to practice any other form of medicine than chiropractic and appear in court again I suspect the court will be considerably less considerate than I think it has been this time."

A certified copy of the information filed against Jacobson and the judgment and sentence of the Court in the instant case, has been furnished the Minnesota State Board of Chiropractic Examiners, and it is expected that Jacobson's license as a chiropractor will be revoked.

Violator of State Narcotic Drug Law Ordered to Serve Prison Term

Re: State of Minnesota vs. Merten J. Stratton.

On December 16, 1941, Merten J. Stratton, forty-five years of age, 914 E. 19th Street, Minneapolis, was ordered to serve a prison sentence previously imposed upon him for violating the Minnesota Uniform Narcotic Drug Act. The order was issued by the Honorable Joseph J. Moriarty, Judge of the District Court of Scott County, Minnesota, where Stratton had pleaded guilty on April 2, 1940, to an information charging him with the crime of obtaining narcotic drugs by fraud and deceit. At the time of entering his plea, Stratton was sentenced to the State Prison at Stillwater for a term of not to exceed five years. The sentence was suspended on the condition that the defendant enter the Federal Narcotic Hospital at Lexington, Kentucky, for treatment for drug addiction. Stratton entered the hospital at Lexington, Kentucky, on May 6, 1940; however, he

refused to stay there and returned to Scott County early in August of that year. Stratton was subsequently committed by the Probate Court of Scott County, to the Willmar State Hospital for further treatment. On May 3, 1941, Stratton was paroled from that institution.

Immediately thereafter Stratton and his wife purchased a small grocery store at 914 E. 19th Street, Minneapolis. In October Mrs. Stratton obtained two prescriptions from two Minneapolis physicians for morphine sulphate. Shortly thereafter a third Minneapolis physician was called to the store and upon being asked for narcotics, not only declined the request, but reported the matter immediately to the Federal Bureau of Narcotics at Minneapolis. In the investigation that followed Stratton admitted to the acting narcotic supervisor that he had obtained part of the morphine sulphate from Mrs. Stratton.

On December 13, 1941, Mr. Julius A. Coller II, county attorney of Scott County, filed a petition with the District Court asking that all previous stays be vacated and Stratton ordered taken to the State Prison at Stillwater to serve his sentence. Mr. Coller's petition was supported by an affidavit from Mr. A. B. Crisler, acting narcotic supervisor for this district. Judge Moriarty immediately made an order revoking the previous stays and ordered the defendant committed. The defendant was promptly arrested and through legal counsel asked for a hearing on the merits, which was given him on December 16, 1941. Following the hearing, Judge Moriarty announced that the order previously entered would stand and that the defendant was to be immediately taken into the State Prison at Stillwater to commence his sentence. The Court fixed the period of his imprisonment at a year and a day.

Stratton has a long record of law violations. On October 18, 1922, he pleaded guilty in the District Court of Ramsey County to forgery in the third degree and was sentenced to a term of not to exceed five years in the State Reformatory at St. Cloud, Minnesota. When Stratton was sentenced in 1922, he stated to the Court that he had been a drug addict for ten years. In 1932, Stratton served 14 months in jail in Los Angeles, California. Stratton admitted that this sentence was in connection with forgery of narcotic prescriptions. Early in 1937, Stratton was sentenced to the Minneapolis Workhouse for ninety days for vagrancy. He was sentenced at that time under the name of Harry Martin. In September, 1937, Stratton was sentenced in Federal Court in Minneapolis to six months in the Minneapolis Workhouse for forgery of narcotic prescriptions. On February 13, 1940, Stratton was sentenced to ninety days in the Minneapolis Workhouse for violating the Minneapolis City Narcotic Ordinance. He was given a suspended sentence of ninety days.

The Minnesota State Board of Medical Examiners wishes to again caution the medical profession about furnishing narcotics to such individuals. It is a violation of state and federal laws for a physician to administer, dispense or prescribe narcotics to anyone except in the bona fide practice of medicine. This presupposes a thorough examination of the patient and a determination that the patient has some substantial ailment for which it is proper to furnish narcotic drugs. The fact that prompt action was taken in the instant case is due, in part, to the good judgment displayed by the Minneapolis physician who declined to furnish Stratton with any morphine, and who promptly reported the matter to the Federal Bureau of Narcotics. Very fine cooperation was received in this case from the Federal Bureau of Narcotics, and particularly from Mr. A. B. Crisler, acting supervisor of that department at Minneapolis, and also from Mr. Julius A. Coller II, County Attorney of Scott County, Minnesota.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

PHYSICIANS LICENSED NOVEMBER 13, 1941

By Examination

- Arthur, Lawrence Milton, U. of Minn., M.B. 1940, Minneapolis General Hospital, Minneapolis, Minn.
- Bayliss, Milward, U. of Chicago, M.D., 1941, 1853 W. Polk St., Chicago, Ill.
- Benson, Allan Joseph, U. of Minn., M.B. 1941, 706 Delaware St. S. E., Minneapolis, Minn.
- Blaisdell, Jack Schoonmaker, Yale U., M.D. 1940, Mayo Clinic, Rochester, Minn.
- Botha, Eleanor, U. of Minn., M.B. 1941, University Hospital, Minneapolis, Minn.
- Brandes, Robert Warren, U. of Minn., M.B. 1941, Minneapolis General Hospital, Minneapolis, Minn.
- Brigham, Charles Fay, Jr., U. of Minn., M.B. 1941, Ancker Hospital, Saint Paul, Minn.
- Brilhart, Kenneth Bortner, U. of Oregon, M.D. 1940, Mayo Clinic, Rochester, Minn.
- Brindley, George Valter, Jr., U. of Texas, M.D. 1939, Mayo Clinic, Rochester, Minn.
- Cooper, Talbert, Emory U., M.D. 1939, Mayo Clinic, Rochester, Minn.
- Corbitt, Richard Wyle, U. of Maryland, M.D., 1939, Mayo Clinic, Rochester, Minn.
- Crawford, James Harry, U. of Minn., M.B. 1938, M.D. 1939, University Hospital Minneapolis, Minn.
- Davidson, John Griffiths, U. of Minn., M.B. 1941, St. Mary's Hospital, Duluth, Minn.
- Downing, George Columbia, Stanford U., M.D. 1940, Mayo Clinic, Rochester, Minn.
- Emerson, Edwin Elroy, U. of Iowa, M.D. 1940, Proctor, Minn.
- Erickson, Donald Johan, U. of Colorado, M.D. 1940, Mayo Clinic, Rochester, Minn.
- Fazen, Louis Edward, Jr., Northwestern, M.B. 1940, M.D. 1941, Ancker Hospital, Saint Paul, Minn.
- Fahlund, Geo. Thorwald Rudolph, Rush Med. Col., M.D. 1938, Mayo Clinic, Rochester, Minn.
- Graham, Frederick Martin, Northwestern, M.B. 1940, M.D. 1941, Mayo Clinic, Rochester, Minn.
- Hammes, Ernest Macfarlane, Harvard, M.D. 1941, Ancker Hospital, Saint Paul, Minn.
- Hanson, Carl Alfred, U. of Minn., M.B. 1940, Minneapolis General Hospital, Minneapolis, Minn.
- Hanson, Norbert Orrin, U. of Minn., M.D. 1941, Ancker Hospital, Saint Paul, Minn.
- Hayden, Charles Gilbert, U. of Minn., M.B. 1940, Minneapolis General Hospital, Minneapolis, Minn.
- Haynes, Allan Louis, U. of Louisville, M.D. 1938, Mayo Clinic, Rochester, Minn.
- Hilton, Hiram David, Rush Med. Col., M.D. 1939, Mayo Clinic, Rochester, Minn.
- Hodgson, Jane Elizabeth, U. of Minn., M.B. 1939, M.D. 1940, Mayo Clinic, Rochester, Minn.
- Hoynes, Robert Maclay, Northwestern, M.B. 1940, M.D. 1941, Mayo Clinic, Rochester, Minn.
- Hultgen, William James, Loyola, M.D., 1941, Minneapolis General Hospital, Minneapolis, Minn.
- Hunter, Oscar Benwood, Jr., Georgetown U., M.D. 1940, Mayo Clinic, Rochester, Minn.
- Jessup, Richard, Johns Hopkins, M.D. 1939, University Hospital, Minneapolis, Minn.
- Johnson, Howard Elmer, U. of Minn., M.B. 1941, Miller Hospital, Saint Paul, Minn.
- Kauvar, Abraham Judah, U. of Chicago, M.D. 1939, Mayo Clinic, Rochester, Minn.
- Keil, Marcus Augustine, U. of Iowa, M.D. 1940, 5231 Xerxes Ave. S., Minneapolis, Minn.
- Kennedy, Thomas James, U. of Minn., M.B. 1941, 1721 Portland Ave., Saint Paul, Minn.
- Keskey, Theodore John, U. of Minn., M.B. 1940, M.D. 1941, Dwight Mfg. Co., Alabama City, Ala.
- Koepeke, Earl Hilmer, U. of Ill., M.D. 1941, Ancker Hospital, Saint Paul, Minn.
- Larson, Ralph Hertrich, U. of Minn., M.B. 1940, M.D. 1941, Tenney, Minn.
- Latchem, Charles Wells, Duke U., M.D. 1939, Mayo Clinic, Rochester, Minn.
- Lima, Ludvig Reinhart, U. of Minn., M.B. 1940, M.D. 1941, Pioneer Hall, University of Minn., Minneapolis, Minn.
- Lovshin, Leonard Louis, U. of Wis., M.D., 1939, Mayo Clinic, Rochester, Minn.
- Martin, William B., U. of Minn. M.B. 1941, Milwaukee Co. Hospital, Wauwatosa, Wis.
- McMillan, James Thompson, III., U. of Minn. M.B. 1941, Presbyterian Hospital, Chicago, Ill.
- Messler, Joseph Dicus, U. of Cincinnati, M.B. 1939, M.D. 1940, Mayo Clinic, Rochester, Minn.
- Meyer, Alfred Charles, Northwestern, M.B. 1939, M.D. 1940, Mayo Clinic, Rochester, Minn.
- Murphy, Joseph Emmett, U. of Minn., M.B. 1940, Minneapolis General Hospital, Minneapolis, Minn.
- Nay, Richard Marion, Indiana U., M.D. 1938, Mayo Clinic, Rochester, Minn.
- Nesse, Gerhard Martin, U. of Minn., M.B. 1941, Ancker Hospital, St. Paul, Minn.

 Walker, Stephen Archie, U. of Minn., M.B. 1940, M.D. 1941, Minneapolis General Hospital, Minneapolis, Minn.

In Memoriam

James Cox Markoe

Dr. James Cox Markoe, pioneer physician in Saint Paul for sixty years, died at his home at the age of eighty-five, November 28, 1941, following an illness of about one year.

Dr. Markoe was born in Saint Paul, August 13, 1856, the son of William and Maria Cox Markoe. His early education was attained at the old Cathedral School in Saint Paul, at the Petit Seminaire in Meximieux, France, and the Seminary of Our Lady of Angels, Niagara Falls, New York. His medical education was received at Jefferson Medical College in Philadelphia, where he obtained the degree of Doctor of Medicine in 1882. Following this he served his internship at the Philadelphia City Hospital. After this was accomplished he returned to Saint Paul and began the practice of medicine in association with Dr. D. W. Hand. Licensing of physicians in the State of Minnesota began shortly after this, and his license was the second issued in the state, a distinction of which he was very proud. Dr. J. Owen, chairman of the Board of Medical Examiners, held license number one.

In 1885 he married Mary A. Prince, daughter of John S. Prince, former Mayor of the City of Saint Paul. To this union, nine children were born, of whom seven are living. The sons are Reverend John P. of St. Louis, Missouri, Reverend Wm. M. of Mankato, Minnesota, James C., Francis A., and Robert P., of Saint Paul,

Minnesota. The daughters are Sister Anne Marie, and Sister Mary Joseph of the Visitation Sisters in St. Louis, Missouri.

Dr. Markoe was the attending physician for many years to the Saint Paul Seminary, The College of St. Thomas, Little Sisters of the Poor and St. Joseph's Orphanage. An intensely religious man, he was extremely conscientious in his medical work. One of his proudest boasts was that he never lost a mother in childbirth in all the years of his practice. He was a member of the Minnesota State Medical Association and the Ramsey County Medical Society and was its president in 1888.

His kindly ministrations endeared him to all his patients and friends. He was always willing to render a benevolent and helping hand to his colleagues in the profession, particularly to the younger members, of whom many learned truths acquired only through years of experience such as his. Possessed of a keen sense of humor he enjoyed life in its simplicity, which made his home an attractive haven to his family, relatives and friends.

JOHN M. CULLIGAN

Lemuel M. Roberts

Dr. Lemuel M. Roberts died October 9, 1941, at his home in Little Falls, Minnesota. He was seventy-nine years of age.

Dr. Roberts was born in Glendale, Ohio, February 3, 1862, the son of Britton and Hester (Martin) Roberts. He attended the public schools of Cincinnati and spent three years at Urbana University, Urbana, Ohio, and one year at the University of Cincinnati. He studied medicine at the Michigan Homeopathic Medical College at Ann Arbor and at the Hahnemann Medical College of Philadelphia, receiving his M.D. degree there in 1883. After graduation he served as physician and surgeon at the *Quapaw* Agency, Oklahoma, until 1885 when he moved to Brainerd, Minnesota.

In 1890 Dr. Roberts went to Little Falls, where he had since practiced except for postgraduate work in London, Berlin and Vienna. He took postgraduate work in Chicago on two subsequent occasions.

In 1887 Dr. Roberts married Helen Gertrude Cooley. Mrs. Roberts died in 1896 and Dr. Roberts was married in 1904 to Ida M. Deppman, who with one son, Clifton Shears Roberts of Seattle, survives.

Dr. Roberts was an active member of the Upper Mississippi Medical Society, the Minnesota State and American Medical Associations for many years. He was at one time vice-president of the Minnesota State Medical Association.

Dr. Roberts was injured March 6, 1936, in an airplane accident near Sleepy Eye while taking a patient to Rochester. He retired in February, 1938, from active practice, in part as a result of the accident.

In every mental institution tuberculosis is a problem of first order. Of the deaths from tuberculosis in the United States, 5.2 per cent occur in mental hospitals while only 15.9 per cent are in tuberculosis hospitals. M. POLLAK, M.D., et al. *Amer. Rev. of Tuberc.*, March, 1941.

INDUSTRIAL HEALTH

Edited by the Committee on Industrial Health and Occupational Diseases

J. L. McLeod, Grand Rapids, Chairman

A. E. Wilcox, Minneapolis

OUR DEFENSE OPPORTUNITY IN INDUSTRIAL HEALTH

THE serious situation in which our nation now finds itself carries with it added responsibilities to the medical profession. Nowhere is the increased load of more direct importance than in Industrial Health. We have recently been told that the essential defense industries will call for the combined labor of fifty-five million individuals. If our all-out effort parallels that of Canada and our other allies, many of these workers will be women. This will further increase the need for intelligent medical coöperation.

The past decade has been marked by increased interest on the part of industrial leaders in the welfare of their employes. On the Iron Ranges of Minnesota some of the most ruthless operators of a few years ago now support whole departments given over to safety planning, safety instruction, accident prevention, good medical aid in accidents and finally medical hygiene. The latter is practiced by yearly physical examinations including chest x-rays and all types of advanced methods for promoting and preserving good health among all employes and their families. What has occurred in this area is but a sample of the progress being made everywhere in industry.

Materials being manufactured for defense will in many instances give rise to new medical problems. Extensive research is being carried on by the United States Public Health Service. The following quotation from its November bulletin covers the matter nicely. "During the current year, the Research Section of the Division of Industrial Hygiene, National Institute of Health, has been engaged in over 125 research projects, and at present has ninety-one such projects in progress. These studies concern the toxicology of organic substances; the toxicology of inorganic substances; industrial pathology and bacteriology; analytical methods and services; changes in pressure, temperature and humidity, including aviation medicine; and physics (physical methods).

Some of these problems will be completed during the current year, and twenty-five additional problems have been outlined for investigation in the near future.

"Over 90 per cent of the present work of the Research Section is associated with problems pertinent to national defense. Particular emphasis is being placed on studies of the toxicity of substances such as explosives, solvents, metals used in airplane and munitions manufacture, and components of synthetic rubbers and plastics, and on investigations relating to the effects of high altitudes and crowded living conditions, as well as to the development of field instruments for the detection and measurement of toxic dusts, fumes, and gases.

"One of the most important problems under investigation is that of the toxicity of explosives. At present, the study is limited to determining the toxic effects of explosives administered by mouth. However, as soon as an experimental chamber now under construction has been completed, the scope of the study will be extended to include the determination of the toxic effects of vapors, fumes, and dusts."

The excellent work in this department being done by Dr. L. W. Foker of the State Board of Health deserves our coöperation. His investigation program is being well received by both industry and labor and should be appreciated by the medical profession. If we are to preserve our system of practice it must be on the basis of full understanding of and service to the public. Nowhere can we gain the support of a more militant group than in the ranks of labor. We must lead the field, not wait and be forced to follow medical dictates from nonmedical forces. Now when all citizens are united in the defense of our country let medicine be armed and at work. Industrial Health offers a more important field today than ever before.

J. LAWRENCE McLEOD.

TRANSACTIONS of the MINNEAPOLIS SURGICAL SOCIETY

OFFICE TREATMENT OF SOFT TISSUE INFECTION SUPPLEMENTED WITH X-RAY THERAPY

R. E. HULTKRANS, M.D.

Minneapolis, Minnesota

(Abstract of article presented for Minneapolis
Surgical Society)

The use of deep x-ray therapy in the treatment of soft tissue infection has proven a valuable adjunct in the office treatment of soft tissue infection. The particular value has been that many of these patients can be kept ambulatory. Cases for radiation are carefully selected largely from experiences we have had in the past.

For the purposes of discussion, this classification of soft tissue infection is used:

1. Paronychia.
2. Furuncles.
3. Boils and small abscesses.
4. Carbuncles.
5. Cellulitis and erysipelas.
6. Miscellaneous.

Paronychia respond so quickly to simple incision that rarely x-ray therapy becomes necessary. In some of the chronic paronychia, however, good results have been obtained.

The use of x-ray in the treatment of furuncles seems to be of value only when given extremely early in an attempt to abort the furuncle and prevent the formation of a pustule and subsequent drainage. After a pustule is formed in a furuncle, x-ray therapy is of little value.

Much the same can be said about small abscesses. We feel that they must receive treatment early if it is to be of value. Some of the boils and small abscesses will break down and localize more rapidly following x-ray therapy, and subsequent incision and drainage will be necessary.

The use of x-ray in carbuncles is probably the oldest form of infection treated by this method. We feel very specifically that all carbuncles should be radiated and then treated immediately afterwards with surgery.

The most spectacular success in the use of x-ray therapy on soft tissue infection undoubtedly occurs in the treatment of spreading types of surface infection, such as cellulitis and erysipelas. A series of seventeen cases of cellulitis was reported, 90 per cent of which recovered under five days without drainage or special dressing.

The treatment of frank erysipelas with x-ray also gives spectacular results, and we have had four such cases with prompt recovery within three or four days.

Miscellaneous types of treatment, which have been tried, are as follows:

One case in which a large knitting needle entered the knee joint and broke off. The patient was not seen until twenty-four hours later, and the possibility of infection was considered. If we incised and explored the knee and subsequent infection developed, the operation might be blamed for such infection, and there would be no way of knowing whether or not the infection had been introduced by the needle. Prophylactic x-ray treatment of the knee joint was given, and a period of two weeks elapsed before exploration of the knee was done. Primary healing occurred without infection. There may or may not have been any benefit from the use of x-ray, but certainly there was no harm.

Chronic infections such as draining sinuses over a long period of time fail almost uniformly to respond to deep x-ray therapy.

Extensive soft tissue infections, particularly in extremities where there is danger of osteomyelitis, likewise fail to respond almost uniformly to the use of deep x-ray therapy.

Conclusions

The use of x-ray therapy in the treatment of soft tissue infections has its greatest value in the treatment of cellulitis- or erysipelas-like infection. Its value in other acute infections depends largely on the promptness with which it is administered after first appearance of symptoms.

Discussion

DR. L. H. FOWLER: Each year at the Students' Health Service, University of Minnesota, I treat hundreds of cases of superficial infections and a few deep cellulitis type of infections. Several years ago, I sent a considerable number of these patients to Dr. Stenstrom for x-ray therapy hoping we could improve our results. I am sorry to say that the results from x-ray therapy in my experience have been very disappointing. I have tried x-ray therapy in all stages of single and multiple furunculosis and cannot see where the process has either been aborted, prevented from spreading, or the usual course materially altered. In my experience, rest, hot wet packs until localization has occurred, followed by adequate incision and drainage is still the best treatment.

BIRTH RATE IS UP, DEATH RATE UNCHANGED

America's birth rate is on the increase, the current vital statistics bulletin of the Commerce Department reveals.

Provisional figures for the first nine months of 1941 for 43 reporting states and the District of Columbia show a crude birth rate increase over the same period last year from 17.9 to 18.9 per 1,000 population.

The crude death rate for October, 1941, for the same states was constant at 9.8 per 1,000 population as compared with October, 1940.—*Science News Letter, December 27, 1941*

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of November 12, 1941

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 12, 1941. Dinner was served at 7 o'clock and the meeting was called to order at 8 o'clock by the President, Dr. John M. Armstrong.

There were 46 members and 2 guests present.

Minutes of the October meeting were read and approved.

There being no business to come before the Academy, the scientific program followed.

NEPHROPEXY FOR THE RELIEF OF PAIN IN ABNORMAL RENAL MOBILITY

Results in 100 Cases, with Particular Reference to the Selection of Cases for Operation

PHILIP F. DONOHUE, M.D.

Dr. Donohue, of St. Paul, read his Inaugural Thesis on the above subject. Lantern slides and charts were shown. (To be published in full at a later date in MINNESOTA MEDICINE.

Discussion

DR. F. E. B. FOLEY, Saint Paul: First of all, I compliment Dr. Donohue on one of the best presentations of the subject of "Nephropexy" I have ever heard.

As Dr. Donohue indicated, I was pretty closely associated with him in management of most of the cases he has presented. This contact began with Dr. Donohue's association with me at the Ancker Hospital about fifteen years ago and continued during the years we were in practice together up to 1934.

In 1929 I presented at this Academy an admission thesis entitled "New Methods for Exposure of the Kidney and for Nephropexy." The original surgical methods described in that paper are the methods employed in these cases of Dr. Donohue. That paper dealt only with the surgical methods I originated and with more or less general consideration of the indications for and the value of nephropexy. It was intended at that time to present at a later date the results achieved by the methods described. Dr. Donohue has relieved me of that job. His careful analysis of the ensuing cases in the hands of us both answers all the questions for which I intended to seek answers.

In the paper twelve years ago I said, "Nephropexy has a well-earned disrepute." Dr. Donohue has not disproved that assertion for nephropexy still has a well-earned disrepute when employed in cases not containing indications for the operation. Despite one's best effort and greatest care, there will be a certain incidence of such cases in the hands of any surgeon who attempts to give nephropexy a fair trial. In this series of carefully studied cases there was complete relief in 50 per cent, moderate relief in 24 per cent, slight relief in 12 per cent, and no relief in 14 per cent. These results are good answer to the blanket condemnation of nephropexy made by some critics. I am sure the results compare favorably with the results of operation for "chronic appendicitis."

DR. L. C. BACON, Saint Paul: Dr. Donohue's exhaustive paper is to be commended and the incision portrayed by him, for the anchoring of a fallen kidney,

is the incision usually employed; but it calls to mind the incision employed by the older Lundholm, with its advantages. His incision was made at the margin of the rectus muscle, the peritoneum was pushed aside, and the kidney anchored. This incision gave him an opportunity to examine the abdominal contents. His dexterity in this avenue of approach was great and gave much evidence to commend it.

DR. GILBERT J. THOMAS, Minneapolis: It is very fortunate that Dr. Donohue has had this opportunity of making a follow-up and subsequent report of the results obtained in the surgical treatment for nephroptosis. Reports of this character are very timely because there has been so much unnecessary surgical treatment done for the relief of so-called floating kidneys.

It is only a few years ago that articles ceased to appear in surgical journals that contained descriptions of new methods for anchoring the kidneys so that these organs would not again become loose.

Many of the failures to relieve symptoms were thought to be due to a faulty technic in the surgical operation which did not fix the kidney permanently in its normal position. The return of symptoms was not due to loosening of the kidney from its anchored position, but to errors in the selection of the proper cases for this operation. One cannot expect to relieve symptoms not produced by a mal-position of the kidney following the anchoring of this organ in a new position.

When a surgeon does an operation for nephroptosis, careful inspection of the uretero-pelvic junction should always be made. In this area anomalous blood vessels, connective tissue bands, and other obstructions may be present and many of these are congenital in origin. These are so important that from my own experience I know that a ptosed kidney would not because of its low position produce obstruction in the ureter if it were not for the kinking that occurred and was produced by a band and anomalous blood vessels that crossed the ureter and therefore held it in position and produced a kink.

The various surgical techniques that are employed to anchor the kidney must take into account the comparative anatomy of the normal kidney in its normal position. If a portion of the fibrous capsule of the kidney is removed from the posterior or convex surface of the kidney, this denuded area will become densely adherent to the adjacent tissues. This union is very firm. I have observed how firm, when I have attempted to remove kidneys surgically that had been previously anchored. A nephrectomy under these circumstances is very difficult. The kidney capsule must be removed by sharp dissection.

DR. MOSES BARRON, Minneapolis: I was very much impressed with the large series of cases reported tonight and the very favorable outcome resulting from nephropexy. This is quite contrary to the opinion I have always held on the importance of nephropexy for nephroptosis. We see cases of nephroptosis very commonly. It is generally stated that from five to fifty per cent of the cases of women alone will show a descent of the kidneys, usually the right. Some of these kidneys are easily felt low down in the abdomen. Most of these patients do not show any symptoms at all as a result of the ptosis, but many of them have symptoms. In my experience, most of those who do show symptoms have an associated general enteroptosis or Glénard's disease. In cases where there is a general enteroptosis, it is doubtful if the symptoms would be relieved by mere fixation of the kidney. Dietl, in 1864, described this condition which later was given the name of Dietl's

crisis. He gave a very accurate description of the symptoms and findings. He stated that his cases were promptly relieved by the application of abdominal belts. Many of us feel that this is true. Properly applied abdominal supports, with a pad in the region of the kidney, will give good results because by this means we give support to the loose abdominal wall at the same time and this prevents the sagging of the abdominal viscera. There is no doubt that some of these cases should obtain relief from nephropexy alone.

I happen to have had a very unusual case which made me interested in this subject many years ago. In 1922 a man came with a variety of complaints of pain in the abdomen for which he had had several operations but without relief. He had had his appendix removed and his gall bladder excised. When I saw him, he apparently had reached the stage where the diagnosis was not so very difficult because his right kidney had descended so that it was easily palpated, especially during an attack. When x-rays were made they showed a very sharp kink of about 45 degrees at the pelvic ureteral junction. The patient was given a belt and instructed to wear it continuously. From then on, he had no more trouble. The belt gave him complete relief.

I feel that many of these patients get good results by wearing properly-fitted belts. I think that the essayist himself tonight showed that one of his patients had good relief after such a support was applied.

DR. FOLEY: As a matter of fact, this is not a "large series of cases." The series covers a period of sixteen years and was supplied by the urologic service of an 800-bed charity hospital—the Ancker, the private prac-

tice of Dr. Donohue, and my own private practice. The 100 cases forming Dr. Donohue's material came from these three sources over a period of sixteen years, which actually is only eight cases a year. So, in proportion to the volume of the source, the actual number of cases is relatively small.

DR. DONOHUE (closing): Dr. Foley has already said what I was going to say in reply to Dr. Barron's comments concerning the occurrence of nephroptosis in cases of general visceroptosis. Visceroptosis was not present in the series just reported, but the condition was found on x-ray examination of the gastrointestinal tract in other cases not treated by nephropexy. Referring to the use of a kidney pad instead of performing nephropexy, Hinman has shown by urography that these pads are often completely ineffective in restoring the kidney to a favorable position in the renal fossa. In the cases with fixation of the upper ureter by inflammatory adhesions or anomalous blood vessels, the pad hardly could be expected to affect the mal-relationships between the kidney pelvis and the ureter. The use of pads in the treatment of nephroptosis is considered passé by many surgeons. The belt mentioned in case No. 14 was an orthopedic sacroiliac belt and was not a supporting belt for the abdomen.

I want to thank the members for their kind discussions of my paper.

The meeting adjourned.

E. V. KENEFICK, M.D.,
Secretary

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR JANUARY

The Minnesota State Medical Association broadcasts weekly at 10:45 o'clock every Saturday morning over Station WCCO, Minneapolis; Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Director of Postgraduate Medical Education, Medical School, University of Minnesota.

January 3—Thyroid Gland
January 10—Pituitary Gland
January 17—The Pancreas
January 24—Adrenal Gland
January 31—Dental Health Education

trips on Wednesday, January 14. A clinical program of a practical nature has also been arranged at the University of Illinois College of Medicine for the same date.

MINNESOTA PATHOLOGICAL SOCIETY

The program for the January 20 meeting of the Minnesota Pathological Society will include the following papers:

"Orthostatic Hypotension" by Drs. Philip Hallock and Gerald T. Evans.

"Transfusion Reactions Due to Rh Factor" by Dr. G. N. Aagaard.

NINTH E. STARR JUDD LECTURE

Dr. Frederick A. Collier of Ann Arbor, Michigan, Professor and Director of the Department of Surgery at the University of Michigan Hospital, will give the ninth E. Starr Judd lecture at the University of Minnesota in the Chemistry Auditorium on Wednesday, January 21, 1942, at 8:15 p.m. The subject of Dr. Collier's lecture is "A Review of Studies on Water and Electrolyte Balance in Surgical Patients."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in surgery a few years before his death.

CONGRESS ON INDUSTRIAL HEALTH

The fourth annual Congress on Industrial Health, sponsored by the American Medical Association, will be held Monday and Tuesday, January 12 and 13, 1942, at the Palmer House in Chicago. The meetings are open to physicians and others interested in industrial health. A dinner and round table discussion intended primarily for state and county medical society committees on industrial health will be held Monday evening. Addresses will occupy morning and afternoon sessions. Those interested in details of industrial medical department administration will be enabled to make field

CLAY-BECKER MEDICAL SOCIETY

Dr. H. G. Rice of Moorhead is the newly elected president of the Clay-Becker Medical Society, which held a joint meeting with the Auxiliary in Moorhead, December 17.

Dr. O. O. Larsen of Detroit Lakes was named vice president; and Dr. E. G. Ingebrigtsen of Moorhead, secretary-treasurer. Dr. J. W. Duncan of Moorhead was elected delegate to the state medical association convention.

Guest speaker at the meeting was Dr. H. Z. Giffin of Rochester, president of the state association, who addressed members on "Our Part in National Defense." He also spoke on "Certain Blood Diseases," and led a discussion on "Anemias."

GOODHUE COUNTY MEDICAL SOCIETY

Dr. L. A. Steffens of Red Wing was elected president of the Goodhue County Medical society, December 18, following a joint dinner meeting and Christmas party with the Auxiliary at the St. James hotel in Red Wing.

Dr. R. V. Sherman was chosen vice president; Dr. R. F. Hedin, delegate; and Dr. M. W. Smith, alternate delegate. All are of Red Wing.

Dr. Walter Schafer of Zumbrota was admitted to membership.

KANDIYOHI-MEEKER-SWIFT COUNTY MEDICAL SOCIETY

At the regular meeting of the Kandiyohi-Meeker-Swift County Medical Society held in Willmar, December 17, the following officers were elected: Dr. F. P. Frisch, president; Dr. D. L. Jacobs, vice president; and Dr. E. H. Frost, secretary. All are of Willmar.

Dr. Hans Johnson of Kerkhoven is the retiring president.

WASHINGTON COUNTY MEDICAL SOCIETY

Officers elected at the annual meeting of the Washington County Medical Society, December 9, were: Dr. Ray G. Johnson, president; Dr. Carnot H. Sherman, first vice president; Dr. George McC. Ruggles, Forest Lake, second vice president; Dr. E. Sydney Boleyn, secretary-treasurer and also delegate. Dr. Wade R. Humphrey was named alternate.

Elected censors were Drs. J. W. Stuhr, R. J. Josewski and E. V. Strand of Bayport.

RAMSEY COUNTY MEDICAL SOCIETY

Dr. W. R. McCarthy of Saint Paul was chosen president-elect of the Ramsey County Medical Society at its annual election of officers, November 24. He will take office in 1943, succeeding Dr. Carl B. Drake, who serves as president during 1942.

Dr. James C. Ferguson was elected vice president and Dr. Joseph M. Ryan, secretary-treasurer of the society for 1942.

Dr. Joseph F. Borg, retiring president, presided at the meeting which was attended by approximately 125 members of the organization.

Members were also elected to the advisory, library, laboratory, judiciary committees, the Boeckmann library building fund committee, and as delegates and alternates to the annual state convention.

RED RIVER VALLEY MEDICAL SOCIETY

Dr. D. V. Boardman of Twin Valley was named to head the Red River Valley Medical Society at its annual meeting in Crookston, December 11. Dr. A. S. Berlin of Hallock was elected vice president, and Dr. C. L. Oppegaard of Crookston was renamed secretary-treasurer.

As delegates to the state medical convention the physicians elected Dr. J. F. Norman of Crookston and Dr. H. M. Blegen of Warren.

The election followed a banquet at the Hotel Crookston, which was attended by physicians and their wives. The Auxiliary was entertained at the home of Mrs. C. G. Uhley during the evening, while physicians heard a medical paper on "Anemia" presented by Dr. H. Z. Giffin of Rochester, president of the state association.

WOMAN'S AUXILIARY

MRS. JOHN J. RYAN, *President*
Saint Paul, Minnesota

MRS. L. R. BOIES, *Publicity Chairman*
Knollwood, Hopkins, Minnesota

STATE BOARD MEETING

The Executive Board of the Women's Auxiliary to the Minnesota State Medical Society met Friday, October 17, at the University Club in Saint Paul, with Mrs. John J. Ryan, the president, presiding. Mrs. Roscoe E. Mosiman of Seattle, Wash., president of the National Auxiliary, was present. Reports were given by the officers and committee chairmen, after which the meeting was adjourned for luncheon, to be reconvened later.

The luncheon, also held at the University Club, had been arranged by Mrs. Lloyd G. Dack, Saint Paul. Forty-eight people were present. Among those were Mrs. Wengart, State program chairman for Nebraska, and Mrs. Beck, State Auxiliary president for Idaho.

Mrs. Mosiman gave an inspiring talk on the importance of being Auxiliary members and the purposes of the Auxiliary. She spoke of women in history and major problems they had been confronted with, immigration in colonial days with its effect on living standards, the abolition movement, temperance, and the establishment of the 18th amendment.

"What can we do today as women through our Auxiliary? We must have the will to do, and help with our national health problems, let us be well informed in this regard, be readers of *Hygeia*, the health maga-

zine of the A.M.A., get others to read it and place it in centers where it will be read."

Too, there are many ways to help in the defense program:

1. By aiding physicians' families near camps, if we are near those camps.
2. Making studies of Pan-American relations.
3. Helping with the Nutrition Program by studying problems of high food prices, working out adequate diets for low income groups, and studying propaganda in food advertisements.
4. Studying the problem of poor health from the lack of good food.

Auxiliary members, Mrs. Mosiman felt, have a real duty to perform locally and nationally, if they will.

The Board Meeting continued after luncheon with reports from the following counties: Goodhue, Hennepin, Nicollet-Le Sueur, Mower, Ramsey, Red River Valley, St. Louis, Scott-Carver, Stearns-Benton, Upper Mississippi, Wabasha, Washington, West Central, Wright, Olmsted-Houston-Fillmore-Dodge, Rice.

Mrs. John J. Ryan, Saint Paul, entertained for Dr. and Mrs. Roscoe Mosiman, Seattle, Wash., at a dinner party, Thursday, October 16. Prominent local Auxiliary members and their husbands were guests.

COUNTY NEWS

Olmsted-Houston-Fillmore-Dodge

Mrs. M. J. Anderson, Rochester, Minn., president, has appointed the following chairmen for the year:

Mrs. T. B. Magath, legislation
Mrs. C. W. Rucker, public relations
Mrs. M. W. Binger, publicity
Mrs. J. E. Crewe, local health
Mrs. L. P. Howell, bulletin of the A.M.A. Auxiliary
Mrs. J. H. Tillisch, program
Mrs. L. M. Randall, telephone

St. Louis

St. Louis County medical women are busy not only in Auxiliary work, but in other varied activities, as the following will show. Mrs. W. N. Graves has had an active part in the Duluth branch of the Committee to Defend America; Mrs. P. G. Borman, Mrs. A. O. Swenson, Mrs. D. W. Wheeler, in organization of the Women's Institute; Mrs. A. E. Walker, Mrs. L. R. Gowan and Mrs. D. W. Wheeler in the Duluth Association for the Physically Handicapped; Mrs. Charles Goodman in the Talmud Torah Sisterhood; Mrs. Philip N. Bray, Mrs. M. F. Fellows in the College Woman's Club; Mrs. A. T. Laird in Y.W.C.A. Household Employment Project; Mrs. M. H. Tibbets in Community Fund Drive.

The first meeting of the Auxiliary for the season was held at the Duluth Woman's Club, October 14, at 1:00 p.m., with Mrs. P. S. Rudie, president, presiding.

The officers for the year include:

Mrs. D. W. Wheeler, president-elect
Mrs. A. J. Bianco, vice president
Mrs. G. A. Hedberg, treasurer
Mrs. F. T. Becker, recording secretary
Mrs. John Butter, corresponding secretary

Ramsey

Ramsey County Auxiliary had its first meeting of the year at the home of Mrs. A. F. Arnquist, 1184 Orange Avenue, Saint Paul. Mrs. A. W. Lilly, Hudson, Wisconsin, very ably spoke on the Red Cross. Dr. John Lepak, of the Ramsey County Medical Society, also spoke, and Mr. John Myhers, of the Saint Paul Civic Opera Association, sang. At the tea following, Mrs. E. M. Hammes and Mrs. John J. Ryan poured.

Hennepin

Women of Hennepin County Medical Auxiliary have had a very intensive entertainment program this fall for women in other groups. The International Medical Assembly, which met the middle of October in Minneapolis, meant much work for the Auxiliary members. At the style show and luncheon at Dayton's, 250 women attended; for the Tour of the Radiation Department at the University Hospital and luncheon at Coffman Memorial Union, there were 125 present; for the luncheon and local talent program at Interlachen Country Club, 236 made reservations.

Closely following this week of activities, came the Public Relations Meeting, Friday, November 7, which was held at the Medical Arts Lounge and Assembly rooms. Mrs. F. S. McKinney, president, presided, and Mrs. Harlow Hanson made arrangements for the meeting. Mrs. R. C. Logefiel was tea chairman, and Mrs. H. W. Quist, and Mrs. C. A. Undine were hostesses. Invitations included representatives of many clubs, and in all 200 attended.

An educational movie on the "Control of Cancer," from the U. S. Public Health Department, was shown and the Auxiliary octet favored the audience with some excellent selections. The highlight of the meeting was a very comprehensive talk by the popular Dr. W. A. O'Brien, on "Modern Public Health Achievements." He presented interesting facts on the advance of medicine in the use of drugs, such as the sulfonamides in infections, the progress in Public Health, i.e., in smallpox and tuberculosis control; however, Minnesota, because of the "anti" groups, is one of four states in the Union which does not have compulsory vaccination and, as a result, has more cases of smallpox and deaths than any place in the country. Preparation for surgery and postoperative care have become as important as the actual surgery. Regarding pregnancy, nutrition has become a most important factor in labor for the mother and later in its effect on the health of the child. He spoke of the advance in dentistry, presenting the fact that "dental neglect is more expensive than dentistry." Cancer is curable. The importance of proper nutrition cannot be over-emphasized, according to Dr. O'Brien. Medicine has advanced, and a presentation of these facts only more firmly substantiates this statement.

Since black fabrics are depressing, special efforts to develop *black-out fabrics* that are more attractive indoors have been made in England.

The S.M.A. Corporation **ANNOUNCES** *Biotin*

METHYL ESTER
($C_{11}H_{18}N_2O_3S$)

Previously Unavailable Factor of the **B-COMPLEX**

• Crystalline Biotin methyl ester, isolated and purified in our laboratories, is now ready for distribution in limited quantities for research purposes. This previously unavailable factor of the vitamin B complex is offered as a solution quantitatively prepared from crystalline biotin methyl ester and as such is suitable for standardization procedures. It is not available in dosage form, but is supplied in 1 cc. ampules, each containing 25 micrograms, for investigational use only.

A review of the literature on Biotin, prepared by our technical staff, is available in booklet form to those interested in nutritional research.

Authors of a book, "Communicable Disease Control," recently off the press, are Dr. Gaylord W. Anderson, head of the Department of Preventive Medicine and Public Health at the University of Minnesota Medical School, and Miss Margaret G. Arnstein, formerly associate professor in that department. Miss Arnstein is now district supervising nurse in the New York State Department of Health.

THE Myrick INHALATOR

Operates
on a
new
principle

Delivers warm,
moistened air.
Is safe and easy
to use,
simple and
efficient.

Instead of projecting a jet of hot steam into the patient's face, or enclosing the jet in a hood or cone, the steam from the generator of the inhalator

is passed through an injector which draws into the stream of vapor a predetermined amount of cool air. This cools the steam to an acceptable temperature, at the same time removing excess moisture and automatically returning it to the generator. The patient may be placed in the direct path of the vapor stream and is sure to receive a steady flow of cooled, highly saturated vapor—restful and extremely beneficial.

The use of the Myrick Inhalator is in cases of acute rhinitis, rhinosinusitis, pharyngitis, tracheitis, laryngitis, bronchitis, after thyrotomy, laryngectomy and tracheotomy and in any postoperative case where there is indication of developing, or already present, respiratory tract infection.

Container accommodating 1½ gallons of water, electric heating unit, nichrome wire with sensitive thermostatic control, which automatically cuts off the current, steam-and-air injector and adjustable flexible metal inhalator tube, with medicants cup.....

Eight Rochester and five Duluth medical naval reserve officers have been ordered to active duty.

The Rochester men reported December 29 for duty at the new naval hospital at Corona, California. Reporting were Dr. W. McK. Craig, neurosurgeon; Dr. H. K. Gray, abdominal surgeon; Dr. A. M. Snell, physician; Dr. H. H. Williams, ear, nose and throat specialist; Dr. Harry M. Weber, radiologist; Dr. H. B. Macey, orthopedist; Dr. E. H. Cook, urologist, and Dr. A. H. Baggenstoss, pathologist.

Destination of the Duluth doctors was announced as "confidential." Those who reported are: Lieutenant Commanders D. W. Wheeler, P. S. Rudie, M. H. Tibbetts, L. R. Gowan and M. F. Fellows.

* * *

Dr. E. M. Jones of Saint Paul was elected first vice president of the Western Surgical Association, and Dr. Harry B. Zimmermann, also of Saint Paul, was re-elected recorder when that association held its annual meeting in Saint Paul last month. Dr. Zimmermann was in charge of arrangements for the session.

Other officers elected were: Dr. Walter D. Gatch

DEPENDABLE SCLEROSIS

for Varicose Vein Injection —

A rapid and dependable sclerosing effect is produced with Sodium Morrhuate 5% Solution with Benzyl Alcohol (Ulmer). When properly injected, it usually does not produce cramps or discomfort. Necrosis is unlikely to occur in the event of slight accidental perivenous injection. It has a relatively low toxicity when the correct posology is employed. Systemic reactions are rare. Its low viscosity permits injection with a small needle.

Write for booklet MM142 which gives the accepted, approved technique.

In economical serum-capped vials:

Dr. Ole M. Heiberg, who has been in private practice in Manhattan, Kansas, since 1938, joined the staff of the Worthington Clinic in Worthington, December 26.

A native of Twin Valley, Minnesota, Dr. Heiberg was graduated from the University of Minnesota Medical School. He was a teaching fellow at the University of Minnesota department of internal medicine, stationed at the Minneapolis General Hospital until 1938, when he went to Manhattan to practice.

At the Worthington Clinic Dr. Heiberg is succeeding Dr. Ira H. Wilson, who recently was called into the military service.

* * *

Dr. Howard F. Claydon, who has been practicing in Zumbrota since 1930, has become associated with his father, Dr. L. E. Claydon, in the Claydon Clinic at Red Wing.

The Clinic, founded by the late Dr. Donald R. Claydon, has been operated the past several months by Dr. L. E. Claydon, who took charge following the death of his son. Because he has found the duties too arduous, he has sought the aid of his son, Dr. Howard F. Claydon, brother of the founder.

Dr. Howard Claydon will continue to maintain of-

fices in Zumbrota, and will return there two days a week, Mondays and Fridays.

Dr. E. M. Baldigo, who has been associated with the Claydon Clinic for a number of years, will remain on the staff.

* * *

Dr. Herman E. Hilleboe of Saint Paul, chief of the medical unit of the state division of social welfare, reported January 1 to the United States Public Health Service in Washington to undertake public health work in connection with defense activities.

Dr. Edwin J. Simons of Swanville, formerly of Bemidji, has been named head of the medical unit on a part-time basis to replace Dr. Hilleboe. A graduate of the University of Minnesota medical school in 1924, Dr. Simons has practiced in Swanville since graduation with the exception of one year in public health work in clinical tuberculosis on the staff of the Minnesota State Sanatorium in 1926. He is also a graduate of Annapolis Naval Academy.

Dr. Hilleboe was commissioned as an assistant surgeon in the United States Public Health Service, June 16, 1939, and since that time has been assigned to the state of Minnesota on request of Governor Stassen. As chief of the Minnesota medical unit, he developed an integrated medical care program which embraces general medical care for assistance and relief recipients, the crippled children's program and supervision of county tuberculosis sanatoria and the state sanatorium at Walker.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

THE TOXEMIAS OF PREGNANCY. William J. Dieckmann, M.D. Associate Professor of Obstetrics and Gynecology, University of Chicago; Attending Obstetrician, the Chicago Lying-In Hospital and Dispensary; Attending Gynecologist, Albert Merrit Billings Memorial Hospital of University of Chicago; Associate Editor of American Journal of Obstetrics and Gynecology; Co-chairman of the Conference on Eclampsia, United States Department of Labor, Children's Bureau, 1941. 521 pages. Illus. Price, \$7.50, cloth. St. Louis: C. V. Mosby Co., 1941.

IMMUNOLOGY. Noble Pierce Sherwood, Ph.D., M.D., F.A.C.P. Professor of Bacteriology, University of Kansas, and Pathologist to the Lawrence Memorial Hospital, Lawrence, Kansas. 639 pages. Illus. Price, \$6.50, cloth. St. Louis: C. V. Mosby Co., 1941.

THE MARCH OF MEDICINE. New York Academy of Medicine Lectures to the Laity, 1941. Various authors. 154 pages. Illus. Price, \$2.00, cloth. New York: Columbia University Press, 1941.

TREATMENT OF THE PATIENT PAST FIFTY. Ernest P. Boas, M.D. Associate Physician Mt. Sinai Hospital, New York City; Chairman, Committee on Chronic Illness, Welfare Council New York City; Assistant Clinical Professor of Medicine, Columbia University. 324 pages. Illus. Price, \$4.00, cloth. Chicago: Year Book Publishers, Inc., 1941.

RADIATIONS AND WAVES—Sources of Our Life. Georges Lakhovsky. Professeur d'Oscillo-Thérapie de l'Institut Physique Biologique de Paris. 139 pages. Illus. Price, \$2.50, paper cover. New York: Emile L. Cabella, 1941.

SYNOPSIS OF ALLERGY. Harry L. Alexander, A.B., M.D., Professor of Clinical Medicine, Washington University School of Medicine, St. Louis; Editor of the Journal of Allergy. 246 pages. Illus. Price, \$3.00, flexible binding. St. Louis: C. V. Mosby Co., 1941.

SYNOPSIS OF GENITOURINARY DISEASES. Austin I. Dodson, M.D., F.A.C.S. Professor of Genitourinary Surgery, Medical College of Virginia; Genitourinary Surgeon to the Hospital Division, Medical College of Virginia; Genitourinary Surgeon to Crippled Children's Hospital; Urologist to St. Elizabeth's Hospital; Urologist to St. Luke's Hospital and McGuire Clinic. 302 pages. Illus. Price, \$3.50, flexible binding. St. Louis: C. V. Mosby Co., 1941.

THE DOCTORS MAYO. Helen B. Clapesattle. 822 pages. Illus. Price \$3.75. Minneapolis: University of Minnesota Press, 1941.

There are two stories to be told: the lives of the men themselves and the growth and development of the great institution they founded and then endowed to ensure the continuance of the benefits conferred upon mankind. The careers of the three Mayos and the unfolding of the steps by which their great work was

accomplished are of necessity closely interwoven, and in this volume are set forth by the biographer with a wealth of detail and a painstaking gathering of information from innumerable sources, reminiscent of the massive story of Lincoln by Sandburg.

The father, William W. Mayo, was of English birth and descent, a member of the same social class in England as the Pilgrim Fathers who settled New England, with whom he shared the important characteristics of courage, integrity, and tenacity of purpose. Coming to the United States in 1845, at the age of twenty-five, he took up the study of medicine partly under a preceptor, but also in one of the small proprietary medical schools with which the Middle West was afflicted at that time. In 1851 he married, his wife having been born in Michigan. Settling in Lafayette, Indiana, only to be driven away in a few years by the intermittent fever from which few escaped in those days, he made his way to Minnesota, reaching Saint Paul in the summer of 1854, where Mrs. Mayo soon joined him. After a stay in Le Sueur, where Will Mayo was born in 1861, he finally came to Rochester in 1864; here Charlie Mayo was born the next year.

Dr. Mayo soon became the leading medical man in southeastern Minnesota, gaining a high reputation as a surgeon particularly, and called in to operate by his fellow practitioners in cases they feared to tackle themselves. As the relation of infection to germs became

recognized and the methods of antisepsis and afterwards of asepsis were established, surgery began to invade the cavities of the body, and Dr. Mayo was among the first to do abdominal surgery successfully in southern Minnesota.

Thus when Dr. Will, in 1883, and Dr. Charlie, in 1885, came to Rochester to begin the practice of medicine, they joined their father in work well established, having the inestimable advantage of beginning surgical work at once as his assistants, enabling them to stand beside the table during operations instead of looking on from benches at a distance. Soon they began to do operations themselves serving as assistants to one another, meantime getting practical experience in general medicine by answering calls and taking care of office practice as far as the patients would permit.

Although there was nearly four years difference in their ages the two boys were from the start inseparable companions, and just as they shared their plays in boyhood they afterward shared their work, their incomes, and the honors that came to them; and the homes they built were side by side and communicating; a most unusual partnership, recognized by the public, who went to Rochester to see "the Mayos," not Dr. Will or Dr. Charlie.

Despite the fact that patients soon came to them from an ever widening circle, they took proper steps to make themselves known. In 1888, this reviewer as one

of a committee to welcome to Saint Paul those coming to a meeting of the Minnesota State Medical Society, remembers shaking hands with two very young men as they got off the train from Rochester; and afterwards, as editor of the local medical journal he published some of their earliest writings. As they joined one medical society after another they were constant attendants at meetings, and their modest yet intelligent and vigorous discussions of papers read attracted attention from the start. Each year at least one of them visited a surgical center and brought back new ideas in technique. The list of the surgeons whose methods they studied includes the names of all those who became famous at the end of the last century. Later, when the visits were extended to Europe, they met and watched the work of the great surgeons of Great Britain and the Continent.

Once started rolling, the snowball of reputation and practice grew rapidly. They took larger offices and added partners to take care of the large business; also a man to handle the finances. At about this time hackmen meeting trains at Rochester greeted the arriving passengers "Take you to the Cook Hotel and to Dr. Mayo's office." It was not much later that Dr. Will said in despair to a Saint Paul friend that they had tied a millstone about their necks and did not see how they were going to carry it. As early as 1904 their anesthetist reported 11,000 administrations. The Mayo Clinic, organized in 1909, moved into its own building in 1914 and the work was divided into numerous departments, each with its own head. The present building dates from 1928.

It is a common observation that men who have achieved greatness in one line of activity would have been equally famous in another pursuit. If turned to commerce the genius that built the Mayo Clinic might have equalled the achievement of A. T. Stewart or of Marshall Field. In the army it might have produced a Napoleon, in the navy a Nelson. One of the notable characteristics of this genius is to make a wise selection of lieutenants. The Mayos owe much of their success to having joined to themselves such men as Graham, Plummer, Wilson, Judd, Rosenau, Beckman, Henderson, Adson, some of whom still continue the work.

Although the Clinic's payroll was a long one, where all from the heads down were on salaries, the surplus soon ran into millions, and the Mayos made preparations to carry out a long cherished plan, to return the money to those from whom it came in the form of opportunities for advanced medical education and for research. With some difficulty a junction was made with the State University Medical School and the Mayo Foundation was established, enabling students of medicine to profit by the large number of patients who consult the Clinic. A large sum of money in the hands of trustees assures the perpetuation of its benefits.

Thus the work of the Mayos lives after them. The old doctor died in 1911, the sons in 1939; brothers united all through their lives they were barely separated by their deaths, two months apart.

W. DAVIS.

CASE HISTORY No. 102

CHEILITIS FROM LIPSTICK

Mrs. P. P. W.—Symptoms: Lips fissured, scaling and dry. Advised all cosmetics be discontinued. After one week condition cleared. Patient asked for and permitted use of lipstick. Eruption reappeared. Patch tests revealed bromo acid in lipstick used reacted positively. AR-EX non-permanent lipstick prescribed. After 3 years' use, with subsequent resumption of all other cosmetics, no cutaneous reactions recurred.

AR-EX offers ethical beauty aids, free from known irritants and allergens.

Will sell reasonable. Good reason for selling. Service and installation arranged. Write: Dr. George E. Brown.—Pine City, Minn.

We must recognize the fact that tuberculosis begins in the human body when the tubercle bacillus is first lodged in the tissues and whatever occurs subsequent to this is largely beyond our control. The disease may be interrupted permanently by the body's defense mech-

anism soon after it begins; it may be interrupted temporarily on numerous occasions but eventually may reach its ultimate goal by destroying parts or even the life of the body.—J. A. MYERS, M.D., Annual Meeting, National Tuberculosis Association, 1940.

Effective, Convenient and Economical

THE effectiveness of Mercurochrome has been demonstrated by twenty years' extensive clinical use.

For the convenience of physicians Mercurochrome is supplied in four forms—Aqueous Solution for the treatment of wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

Mercurochrome, H.W.&D.

(dibrom-oxymercuri-fluorescein-sodium)

is economical because solutions may be dispensed at low cost. Stock solutions keep indefinitely.

Mercurochrome is accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

SULFATHIAZOLE

Winthrop

Subjected to Rigid System of Controls

PNEUMOCOCCUS INFECTIONS . . . Thousands of cases of pneumococcus pneumonia have responded with dramatic promptness to Sulfathiazole.

STAPHYLOCOCCUS INFECTIONS . . . With Sulfathiazole the mortality rate of staphylococcus septicemia has been strikingly reduced.

GONOCOCCUS INFECTIONS . . . Early cessation of discharge and a high percentage of cures have been reported.

Write for literature which discusses the indications, dosage and possible side effects of Sulfathiazole.

HOW SUPPLIED: Sulfathiazole-Winthrop is supplied in tablets of 0.5 Gm. (7.72 grains); also (primarily for children) in tablets of 0.25 Gm. (3.86 grains).

Powder in bottles of 5 Gm., $\frac{1}{4}$ lb. and 1 lb.

A Threefold Story

The selection of Preparations by Luzier is a threefold story . . . beginning with (1) the filling out of the Luzier Selection Questionnaire from which the patron's cosmetic requirements and preferences are determined . . . (2) the selection of suitable preparations . . . and (3) the entering of the patron's name, address, products selected for her, and registration numbers assigned to her, on a registration card for the files at Luzier's, Inc. . . . These three steps serve to illustrate the desire of Luzier's, Inc., and the Distributors of their products to serve the best interests of their patrons.

I WANT MORE PABLUM!

PABLUM
originated
IN 1933

Pablum is a palatable mixed cereal food, vitamin and mineral enriched, composed of wheatmeal (farina), oatmeal, wheat germ, yellow cornmeal, powdered beef bone, sodium chloride, alfalfa leaf, powdered yeast, and reduced iron, thoroughly cooked and dried. Pablum needs no further cooking, and can be prepared directly in the cereal bowl simply by adding milk or water, hot or cold. During the past decade, Pablum has been the basis of many significant clinical studies and is mentioned favorably in numerous medical textbooks and papers. Bibliography on request.

MINNESOTA MEDICINE

Another defense problem solved—

the American soldier's identification tag now carries his blood type.

"TYPE THE BLOOD OF EVERY SOLDIER" was the recent order issued by American Army officers.

To aid the Army surgeons in fitting such a vast blood grouping program into their schedule, Lederle developed a new dried blood serum with important advantages over human serum. Less costly and more stable, this new serum is derived from immunized rabbits. Large amounts of rabbit serum are reduced to small quantities of a stable and uniformly potent powder. The new product results in much greater speed in the agglutination reaction. Now, in an incredibly short time, clumping of the A, B and AB cells is visible to the naked eye.

Among other qualities found in the blood grouping sera are greater accuracy and uniformity of results. Stability is assured; the product lasts indefinitely. The Lederle serum has received Army surgeons' approval. "Blood Grouping Sera (Powdered) Lederle" are in extensive use in the Army camps.

What!— Prescribe Cigarettes?!?

It's protection for smokers
who inhale—

and all smokers do sometimes

RECOGNIZED laboratory tests have conclusively proved the advantage of Philip Morris over other cigarettes, i.e.

The irritant quality of the smoke of four other leading brands averaged more than three times that of the strikingly contrasted Philip Morris.

Further—the irritant effect of such cigarettes was observed to last more than five times as long.*

SAFE CROSSING

The stormy symptoms of the menopause may be greatly tempered by administration of Theelin. Theelin replaces or supplements diminished ovarian estrogen secretion. By so doing it acts as a beneficial influence to help bridge the menopausal period that lies between early ovarian hypofunction and adjustment to the estrogenic deficiency. The clinical case of Theelin rests on more than three hundred published papers and the effective use of millions of doses . . . in the treatment of the climacteric, senile vaginitis, kraurosis vulvae, gonorrheal vaginitis in children, and other conditions related to estrogenic deficiency.

Theelin is a pure crystalline estrogen, standardized in the laboratories of Parke, Davis & Company. Before release, each lot is also standardized physiologically and chemically by the Biochemical Laboratory of St. Louis University.

Theelin Suppositories for vaginal use and Kapseals Theelol for oral administration are available where sustained therapy between injections of Theelin is desired.

Q. Canning's a pretty old method of preserving foods, isn't it?

A. No. On the contrary it's comparatively new. Methods of food preservation, such as smoking and drying fish and meats, are thousands of years old. However, canning was first successfully employed in the early years of the 19th century. The improvements of modern canning procedures are the direct outgrowth of many achievements of modern science. ⁽¹⁾

A New Study

COCOMALT AS SUPPLEMENTARY NOURISHMENT IN TUBERCULOSIS

Clinical Material

Controlled observations* of 118 cases of pulmonary tuberculosis over a period of 12 to 20 weeks.

Controls

COCOMALT tested against milk alone or cocoa flavored milk for supplementary nourishment.

Results

	WEIGHT INCREASE	HEMOGLOBIN INCREASE
COCOMALT Test Group . . .	50%	48%
Control Group . . .	21%	27%

Note that the percentage of patients gaining weight in the test group was more than twice that in the controls.

8-10 WEEKS AFTER THE STUDY WAS CONCLUDED, additional checks were made on several patients. Results—none of the COCOMALT test group showed any significant gain in weight following

discontinuation of the enriched food drink.

More and more physicians are realizing the value of COCOMALT for “defense” diets in certain disease states. COCOMALT contains vitamins A, B₁ and D . . . minerals—calcium, phosphorus and iron. A delicious food drink that even the most difficult appetite will seldom refuse.

COCOMALT
Enriched Food Drink

The art of doing things well

EVERY empty capsule made by Eli Lilly and Company passes under the watchful eyes of a Lilly inspector. When bright light is transmitted through glistening gelatin, minute cracks and bubbles are detected — defects which would detract from the perfection of Lilly Pulvules (filled capsules). An expert inspects 200,000 capsules a day, and while less than one percent is discarded the operation is regarded as an essential safeguard to Lilly Quality.

PRESENT STATUS OF SURGERY OF THE ACCESSORY NASAL SINUSES

CHARLES E. CONNOR, M.D.

Saint Paul, Minnesota

THE modern story of the nasal accessory sinuses begins with the profound anatomical researches of the Viennese and German schools shortly after the middle of the last century. Aided by limitless post-mortem material and a flare for research, men such as Zuckerkandl and Hajek of Vienna, Grünwald of Munich, and Killian of Baden covered the entire field so thoroughly that little has since been added to their work. These studies, concerned solely with gross anatomy, laid the foundation for all later surgical procedure but could not be fully utilized at the time because of technical difficulties; for many years, therefore, the only operations attempted on the accessory sinuses were external, done under general anesthesia, and without any special illumination. The frontal sinus was most frequently opened, occasionally the antrum. Lack of adequate cavity illumination and hemostasis made such procedures difficult and rendered the surgery of the sinuses static for a long time.

So matters stood till the discovery of cocaine in 1885 and adrenalin in 1910; this combination produced such anesthesia and ischemia that the field of intranasal surgery seemed limitless; patients were willing to have almost anything done provided only that it left no visible scar. So was ushered in the so-called "Golden Age" of rhinology when almost anything "went," provided no scar was left.

It ultimately became evident that a restudy of the problem was indicated, not so much in the fields of anatomy or surgical technic, for these were already on a sound basis, but in the fields of physiology and pathology; accordingly much research, initiated in this country and copied abroad,

has been carried on in various university centers for the past decade with most illuminating results. Our understanding of nasal function, the filtering, warming and moistening of the air, the function of smell, has been amplified by the newer knowledge of the function of the mucous blanket, of the cilia, and of epithelial and glandular tissue.

Much of our older therapy with sprays, swabs, and irrigations was revealed as not only not beneficial but definitely harmful, in that it interfered with the mucous blanket and with ciliary activity. We realize now that the delicate nasal membrane will not tolerate strong medication, that the mucous blanket is impervious to many of our favorite remedies, including the old reliable nasal oils, that any germicidal agent strong enough to be effective will work irreparable harm to the mucosa, that irrigations are bad because they wash away the protective mucus, that strong vasoconstrictors, if much used, produce a flabby, thickened membrane productive of permanent nasal obstruction. We have a clearer understanding of the vast amount of work the normal nasal mucosa can accomplish and of the necessity of preserving it intact and interfering as little as possible with its function.

The surgical treatment of sinusitis is unique in that healing of suppuration in a bony-walled cavity must be achieved, with rare exception without ablation of the cavity and with preservation of normal function and cosmetics. Abscesses in soft tissue can be incised and drained; in sinus suppuration this technic is not available and cosmetic considerations are important.

Preservation of normal function means the preservation of the normal sweeping action of the mucous blanket and cilia of the nose and acces-

Read before the Ramsey County Medical Society, Saint Paul, Minnesota, September 29, 1941.

sory sinuses, the most important single factor in the health of these structures. Obviously this means that healing must be accomplished with as little disturbance as possible of the normal mucosa

Fig. 1. Extreme variation in development of frontal and maxillary sinuses. (From J. Parsons Schaeffer.)

of these cavities; this membrane, given a chance by adequate ventilation and drainage, has enormous recuperative power. In the exceptional case, requiring removal of the lining mucosa, the cavity is relined with scar tissue which may be and often is covered with a normal ciliated columnar epithelium quite capable of carrying on the ordinary cleansing functions of cilia and mucous blanket.

Küster, half a century ago, formulated three basic principles of treatment of suppuration in a rigid-walled cavity. The cavity must be opened widely enough to permit adequate inspection, all diseased tissue must be removed, and ventilation and drainage must be secured by a permanent opening, principles just as fundamental today as when formulated. Endless variation in the anatomy and relations of the sinuses determines in part success or failure in the application of these principles and in the preservation of normal function and cosmetics, factors touched on briefly when the surgical treatment of individual sinuses is considered.

The maxillary antrum, of all the sinuses, is the most frequently involved in disease processes and providentially offers the best opportunity to apply Küster's postulates. This is so, largely because the antrum is usually a single cavity,

easily accessible, and without intimate vital relationships which would make its surgical treatment hazardous. The floor of the antrum may be level with, above, or below the floor of the nose. The latter situation usually prevails and makes for some retention of secretion after the most thorough antrotomy. The infraorbital nerve may lie exposed in the roof of the antrum and be injured by the curette; the bicuspid and molar teeth and the nasolacrimal canal in the nasoantral wall may also be injured by too vigorous curettage. The great palatine artery, a branch of the third division of the internal maxillary, may be injured if antrotomy is carried too far posteriorly; bleeding from this vessel is difficult to control (Fig. 1).

Antrum suppuration was first treated by irrigation or insufflation of medicinal agents through the fistula made by extraction of a molar or bicuspid tooth. This method, fulfilling none of the fundamental requirements of treatment, was doomed to failure and soon abandoned. The next step was the removal of part or all of the canine fossa, a procedure technically easy and limited only by the location of the infraorbital nerve above, the position and length of the upper teeth, and the size of the cavity; inspection and removal of diseased tissue was easily accomplished. Ventilation and drainage was at first attempted by making an oral-antral fistula; this was neither easy to do nor always effective. A large opening under the inferior turbinate with closure of the incision over the canine fossa was much more satisfactory and fulfilled the requirement for permanent drainage; this, the Caldwell-Luc operation, has given good results for many years. The principal objection to it is the severity of the reaction and time required for healing. In recent years the tendency has been to reserve it for certain types of cases, marked polyposis, foreign body, malignancy, or cases failing to respond to the simpler operation of antrotomy, the so-called "window-resection."

Antrotomy has been widely used in recent years and has proved effective in simple uncomplicated antral disease. Reports range as high as 85 per cent of successes in properly selected cases. It is technically much easier to do, is followed by very little, if any, reaction, and healing time is shortened. It does not permit as effective application of Küster's postulates as does the Caldwell-Luc. A large antrotomy will, however, permit

fairly satisfactory inspection of the cavity with the antroscope or small mirrors, diseased tissue can be removed with reasonable certainty, using angled curettes, ventilation and drainage is just as satisfactory as with the more radical procedure. The mucosa may not return to normal for several months but a surprising amount of hyperplasia and beginning polyposis will eventually subside. It is the procedure of choice in uncomplicated cases of antrum suppuration. The one essential to success is to make the antrotomy as large as possible.

Operations on the antrum are best done under local anesthesia induced by injection of the sphenopalatine ganglion, intranasal nerve block with cocaine, and local infiltration with novocaine; they may also be done under general anesthesia but bleeding is apt to be troublesome.

The frontal sinus illustrates very well the importance of anatomical factors in treating suppuration in rigid-walled cavities and the truth that when adequate exposure, cleansing, and drainage are secured the results are good. When these essentials cannot be secured the result will probably be poor.

The frontal sinus may vary from a single small cell barely entering the frontal plate to a huge multiloculated cavity, extending from the external angle of one orbit to that of the other, and from the supraorbital margin to the hair line or even further; the nasofrontal duct may be a large straight canal emptying directly into the nose or it may be a narrow tortuous tube emptying indirectly into the nose. The floor of the sinus may contain no cells or it may be completely pneumatized back to the apex of the orbit, bringing the cavity into relation with the optic nerve and muscle cone (Fig. 2).

Problems peculiar to the frontal sinus complicate its treatment. Cosmetic considerations are important; the removal of the supraorbital margin or frontal plate produces, in large sinuses, a very evident and objectionable deformity. Certain cases would be best treated by obliteration of the cavity did not the resulting deformity forbid.

Osteomyelitis of the frontal bone, due to infection of the blood spaces in its diploë, is a serious complication possible in any procedure which attacks the frontal plate and invades these structures. Not infrequently resection of the entire frontal bone is necessary to check it.

A third problem, one of the most difficult of

all, is the maintenance of ventilation and drainage through the nasofrontal duct. A canal which has been enlarged to a diameter of a centimeter may close down in the course of a few weeks till it is

Fig. 2. Very large frontal sinus. (From J. Parsons Schaeffer.)

no longer functioning. Many methods to keep it patent have been tried, such as the use of skin and mucous membrane flaps, silver tubes, or radium. None of these has proved uniformly successful and the final answer to this problem has not been found.

The first approach to the frontal sinus was an opening in the anterior plate, either a small trephine or an extensive resection of the entire structure. When the sinus was limited to the frontal portion of the bone, inspection and removal of diseased tissue was easily accomplished. Maintenance of adequate drainage and ventilation, not so easily secured because the duct was not accessible to treatment, depended largely on its anatomy. Small sinuses could be obliterated by healing from the bottom.

A sinus limited to the frontal part of the frontal bone is not the usual situation; more frequently ethmoidal cells pneumatize the floor of the sinus to a variable degree. There may be only a few small, easily accessible cells or there may be many large cells, pneumatizing the floor of the sinus extensively over the orbit. In the latter case adequate treatment is impossible and the result of direct frontal approach unsatisfactory because of its inability to reach ethmoidal cells in the floor of the sinus and to control the nasofrontal duct.

The next development was the resection of the floor of the sinus, the approach being made through an incision in the eyebrow. This could be used for large or small sinuses, with or without

Fig. 54. (Head XIX.)

Fig. 3. Relation of optic nerve to accessory sinuses. (From J. Parsons Schaeffer.)

extensive ethmoidal development, and rendered the ethmoidal cells and nasofrontal duct much more accessible to treatment. As originally devised, the technic called for a bridge of bone above the supraorbital margin to maintain normal contour, especially in large sinuses.

This operation was hailed as the final answer to suppurative disease of the frontal sinus. But difficulties soon appeared. The bridge was technically difficult to make and retention of secretion often occurred behind it, causing recurrence of symptoms. Ethmoidal cells often proved difficult of access and closure of the nasofrontal duct often marred an otherwise satisfactory result. Osteomyelitis of the frontal bone continued to occur.

Occasionally, in small sinuses, the operation could be performed without making the bridge. This simplified the procedure, allowed satisfactory treatment of both frontal and ethmoidal portions, and was not cosmetically objectionable.

The present trend in the surgical treatment of the frontal sinus is to approach it through resection of the thin portion of the floor, avoiding any trauma to the frontal plate with its attendant dangers of osteomyelitis and cosmetic defects. Such an approach is technically easy, permits satisfactory inspection, cleansing, ventilation and

drainage, and secures as adequate treatment of the ethmoidal cells and nasofrontal duct as any technic we possess. The removal of the frontal plate is reserved for cases in which it is diseased or in which the posterior wall of the sinus must be inspected, e.g., suspected intracranial complication, fracture, malignancy, or those which have failed to respond to previous surgical treatment.

Acute suppurative frontal sinusitis rarely requires surgical treatment. When indicated, usually in cases of acute retention with severe pain or orbital involvement, approach should be made through the floor of the sinus, making an opening large enough to secure drainage from both frontal and ethmoidal portions. General anesthesia is desirable in order to avoid infiltrating an infected field. In such situations drainage is the only consideration, not accurate exenteration of all cells. Surgical procedures on the frontal plate are to be avoided in the presence of acute infection on account of the danger of osteomyelitis. Only definite indications of intracranial complication, such as meningitis or brain abscess, would warrant such measures. Any intranasal operation, such as turbinate resection or ethmoidal exenteration, is strictly taboo in the presence of acute infection.

Such operations, however, have a definite place in the treatment of chronic suppuration of the frontal sinus. They do not, of course, permit the adequate application of Küster's postulates. Inspection of the sinus and removal of diseased tissue from it is not possible; the only thing that can be secured is better ventilation and drainage. Fortunately, these measures control most of the cases of chronic suppuration in the frontal sinus; if they fail, recourse must be had to the external approach above described.

Acute infection calls for general anesthesia in operations on the frontal sinus. In chronic infection, the type usually demanding operation, local anesthesia is the choice because the hemostasis and enlarged field due to shrinking of vascular tissue (turbinates and membrane) define the landmarks and so permit more accurate and safer work. Intranasal nerve block with cocaine, superficial infiltration of soft tissues and deep orbital injection with novocaine produce most satisfactory anesthesia.

The ethmoidal sinus offers more difficulty in the application of the fundamental principles of treatment than does any other, due largely to its

peculiar honeycomb structure and endless and bizarre variation in development. The cells themselves are not directly visible by any method of examination; all that can be seen directly are the regions in the nose into which the various groups open, where their ostia may occasionally be seen with the nasopharyngoscope. The cells may invade the roof of the orbit, overlying that cavity, underlying the anterior fossa, and causing symptoms identical with those of a frontal sinus infection. They may invade the posterior portion of the antrum, giving rise to a so-called double antrum, or wander out into the middle turbinate; they may invade the body of the sphenoid bone, lying above or at the side of the sphenoidal sinus and so acquiring relationship with the optic nerves and commissure. They may lie behind, above, or in front of the pterygomaxillary fossa and its contained sphenopalatine ganglion, so that inflammatory reaction within these cells may cause referred pain anywhere in the field of the fifth nerve; they may be in direct contact with vital structures such as the cribriform plate. The use of x-ray and contrast media occasionally serves to warn us of unusual variations and often gives us a clue as to the best method of surgical attack.

No serious efforts were made to approach the ethmoid surgically as long as general anesthesia alone was available because the free bleeding so induced obscured all landmarks and made any such attempt, either intranasal or external, dangerous. And so it remains today. This one fact explains the universal practice of doing ethmoidal operations, either by intranasal or external route, under local anesthesia; only so can a bloodless field and clear delimitation of landmarks be secured. These, together with brilliant illumination, are the *sine qua non* of ethmoid surgery. True, one occasionally enters the ethmoid using general anesthesia, usually in cases of acute infection with retention and orbital involvement, but accurate exenteration is not attempted, merely drainage. Mosher, professor emeritus of rhinology at Harvard, author, some thirty years ago, of much brilliant original work on the ethmoid, has remarked that ethmoidal surgery worthy of the name always has been dangerous and always will be dangerous. A little reflection on the possible relations of this sinus makes the statement self-explanatory.

Ethmoidal surgery under local anesthesia dates from the discovery of cocaine. The approach

may be either intranasal, or external through the eyebrow and about the inner canthus. If the cells, as seen in x-ray, appear accessible by the intranasal route, this method may be

Fig. 4. Some relations of the sphenoidal sinuses. (From J. Parsons Schaeffer.)

tried. Anesthesia by intranasal nerve-block is very satisfactory; there is no shock or serious reaction associated with the procedure and healing is comparatively rapid. If due regard is had for the vital relationships above described, no accidents should occur. The middle turbinate may be removed after the operation or left intact; many prefer the latter, feeling that sacrifice of vascular tissue is to be avoided if at all possible.

If x-ray reveals cells inaccessible by intranasal approach, the external route about the inner canthus may be used. This also is done under local anesthesia, secured by superficial soft tissue and deep orbital injection of novocaine, and intranasal nerve-block. Such anesthesia is quite satisfactory; the ischemia so produced may be increased, if necessary, by ligation of the ethmoidal arteries. The field should be dry with maximum visibility and accessibility, permitting the examination and exenteration of the sinus cell by cell. Such technic gives the best chance of reaching difficult cells, is safer than the intranasal approach, and results in a scarcely visible scar.

The results of ethmoidal surgery depend on the thoroughness with which the cells are exenterated and this depends, in part, on their accessibility. If they are so situated that Küster's postulates may be attained by one technic or another, the

results will be good, and definite improvement in nasal occlusion, discharge, and headache will be secured. If the cells are reached only with great difficulty and exenteration is incomplete, results will be disappointing.

The sphenoid sinus, lying immediately behind and in close relation with the ethmoidal sinus, may be considered a prolongation backward of that sinus and, from the surgical point of view, a part of it. What has been said, in connection with the ethmoid, about the effect of anatomical characteristics and relationships upon surgical treatment applies with equal or even more force to the sphenoid. Its variations may be just as extreme and bizarre, its relationships just as vital, its surgical approach just as difficult as in the case of the ethmoid. Indeed, some of its recesses and prolongations are completely invisible and inaccessible by any means of approach.

The sinus varies greatly. It may be one small shallow cell, lying entirely on its own side of the sagittal plane, or it may be a huge, multiloculated cavity crossing the midline and giving symptoms on the opposite side of the head. It may enter the perpendicular and orbital plates of the palate bone, approaching the optic foramen and nerve. It may invade the greater or lesser wings of the sphenoid bone, assuming close relations to the superior orbital fissure and its contained structures, especially the superior and inferior divisions of the oculomotor nerve, the trochlear nerve, the lacrimal, frontal, and nasociliary divisions of the ophthalmic nerve, and the abducens. It may approach the foramen rotundum and the contained maxillary nerve or the foramen ovale and mandibular nerve. The sinus is in apposition posteriorly, in at least 50 per cent of the cases, with the optic nerves and commissure; if it is extensively developed posteriorly these structures may lie in the roof of one or both sphenoids. The clinoid processes may be pneumatized with the close approximation of the sphenoidal cavity to the contents of the sella. Dehiscences in the lateral wall of the sphenoid may expose the cavernous sinus and its contents directly to the sphenoidal mucosa and demand great caution in any attempt to remove diseased tissue from the cavity.

The sphenoid, lying deep in the nose, is not easily exposed to view, and part or all of the middle turbinate must be sacrificed to gain access to it. Treatment of suppuration within it involves taking down the anterior wall, partly membrane

and partly bone, or, in stubborn cases, the resection of the bony floor, a structure which may be quite thick and difficult of removal. The principle difficulties in treatment are caused by inaccessible ramifications, such as the pterygoid recess, and by the marked tendency to close of any operative opening in the anterior wall. These openings must be made as large as possible, as in antrotomy, in order to be permanent. Extreme care must be used in removing diseased tissue from its interior. It is evident that, while the problem of cosmetics does not here demand consideration, difficulties, at times almost insurmountable, are encountered in obtaining adequate inspection, in removal of diseased tissue, and in maintaining adequate drainage. When a large enough opening is secured in the anterior wall of the cavity, disease processes within usually subside quite satisfactorily. Limitations upon the operative field and procedures, so characteristic of sinus surgery, are well illustrated.

The discovery, in recent years, of nasal allergy has thrown much light on diseases of the accessory sinuses and has explained many of our failures in the past. It is estimated that about 25 per cent of the patients in ordinary rhinologic practice have in them some element of allergy, a fact we are just beginning to appreciate.

For years nasal allergy paraded under a long list of pseudonyms, hyperesthetic rhinitis, spasmodic rhinorrhea, rhinitis nervosa. We recognize them today as allergic rhinitis. One of the most frequent and baffling types of case in years gone by has been that of nasal polyposis, constantly recurring despite repeated operation. Today we realize that its cure depends, not on surgery, but on the discovery of the offending allergens. True, polypi may result from nasal infection, but such polypi are much more easily controlled by operation and have much less tendency to recur when the infection has been eradicated.

Allergy, of course, does not explain all nasal disease. Acute and chronic infection still take heavy toll of the accessory sinuses and are still amenable, in most cases, to surgical treatment. But we now realize that an uncontrolled allergy will probably vitiate surgical treatment of the sinuses, treatment which should not be undertaken till the allergic factors have been eradicated so far as possible. Naturally, one would not hesitate to initiate surgical treatment in the allergic pa-

tient, in cases of acute infection with retention, orbital abscess, or osteomyelitis. Minor procedures, such as removal of obstructing polypi or resection of deflected obstructing septæ, may also be properly done with good result in allergic cases. Our knowledge of allergy has greatly clarified surgical indications but it has not rendered sinus surgery obsolete.

I have attempted to present very briefly some of the aspects of sinus surgery which are peculiar to it and which explain, in part, some of the failures; I have pointed out the difficulties of satisfying the fundamental requirements of treatment of suppuration in rigid-walled cavities, e.g., adequate inspection, removal of diseased tissue, and establishment of permanent drainage; I have mentioned the bearing which anatomical variations have on the problem, the proximity of vital

structures, the limited field, the difficulties of exposure, and the necessity of frequently solving these problems while paying strict attention to cosmetic considerations.

I believe that the work of the past decade, particularly in physiology, is placing sinus surgery on surer and higher ground and that expectation of further advance is not unreasonable. As we assimilate into the experience of the past some of our newer knowledge of physiology, as the rôle of nasal allergy becomes clearer, as some of the newer surgical technics come into more general use, it should be possible to formulate clearer and more definite operative indications, and to use technical procedures promising a degree of success justifying the measure advocated. This is the hope and expectation of everyone interested in this field.

MINNESOTA'S EXPERIENCE WITH HUMAN ENCEPHALITIS CAUSED BY THE EQUINE TYPE OF VIRUS IN 1938

C. M. EKLUND, M.D., and ALEX BLUMSTEIN, M.D.
Minneapolis, Minnesota

EPIZOOTICS of equine encephalomyelitis have been observed for over seventy years but an etiologic agent was not definitely established until Meyer, Haring and Howitt²⁴ isolated a filterable virus during a California epizootic in 1930. In 1933, TenBroeck and Merrill,³¹ and Giltner and Shahan¹³ isolated a somewhat similar virus during an epizootic in four eastern states. The virus differed immunologically from the viruses which had been isolated in the western areas and the terms eastern and western strains of equine encephalomyelitis virus were introduced. The eastern strain produced a much more fatal type of disease in horses. It has been a general belief that the eastern strain is limited to the region east of the Appalachian Mountains and the western strain to the regions west of these mountains but recently the eastern strain was isolated from the brain of a horse in a Texas epizootic.²⁷

The possibility of human disease being caused by the equine type of virus was first suggested by Meyer²³ in 1932 when he presented three cases

of human encephalitis with a history of close association with sick horses prior to the onset of encephalitis. The first laboratory evidence supporting this suggestion was obtained in connection with a small epidemic of encephalitis occurring in the late summer of 1937 in an area of Minnesota where equine encephalomyelitis was prevalent.⁷ Six cases were reported, two had a fatal outcome, autopsy was done in one case and microscopic evidence of encephalitis was found. Blood was obtained from three of the survivors in January, 1938, and neutralization tests were run by Dr. Carl TenBroeck of the Rockefeller Institute. The serum of the patient most severely ill showed neutralization of the western equine strain. During the summer of 1938 epidemics occurred in various parts of the country and the etiology of the human cases was definitely established by the isolation of the eastern and western strains of virus. In August, 1938, cases of an unusually fatal type of encephalitis appeared in Massachusetts. The first report of the isolation of an equine virus from a human case was that of Fothergill, Dingle, Farber, and Connerly⁹ who isolated the eastern strain of virus from the brain of a child dying in this outbreak. Webster

From the Minnesota Department of Health, Division of Preventable Diseases and the Division of Mental and Nervous Diseases, University of Minnesota Medical School. Read before the Minnesota Society of Neurology and Psychiatry, Sept. 9, 1941.

and Wright³⁵ confirmed the isolation of virus from this case and succeeded in isolating virus from four additional cases. At this time cases were also occurring in California and from the brain of one of these Howitt¹⁹ isolated the western strain of virus. Later she reported the isolation of the western strain of virus from the blood serum of another case. In addition she has reported thirty-two cases (chiefly 1937 and 1938 cases) with sera neutralizing the western strain of virus.²⁰ Breslich, Rowe, and Lehman² in a clinical and pathological report of twenty-three cases seen in the North Dakota epidemic during the summer of 1938, state that neutralization tests were run by Dr. Charles Armstrong with six sera; four neutralized the western strain of virus and one the St. Louis virus. Gareau¹² reported a clinical study of twenty-nine cases occurring in southern Saskatchewan. Fulton¹¹ demonstrated neutralization of the western virus by the serum of one of these cases. In 1939 he received a brain specimen from a patient dying in this same area; from this specimen he isolated the western strain of virus. In Minnesota during 1938 the sera of fourteen cases neutralized the western virus.

From 1938 to 1940 few cases appear to have been recognized. Recently, two studies of 1940 outbreaks of acute encephalitis have been reported which emphasize the close association of the disease caused by the western strain of equine virus and the St. Louis virus. Phillips, Cox, and Fountain²⁵ report the study of an outbreak of encephalitis occurring in northern Colorado during the summer and fall of 1940 among humans and horses. Neutralization tests were run with sera from fourteen human cases; the sera of seven showed protection against the St. Louis virus; one of the seven showed equal protection against the western strain of virus. Of sera from seven horses that had encephalomyelitis, all showed protection against the St. Louis virus and five also against the western equine virus. In an accompanying paper Cox, Phillips and Kirkpatrick⁴ showed that horses were susceptible to intracerebral inoculation of the St. Louis virus and that recovery from infection with the western strain of virus did not protect against infection with the St. Louis virus.

Hammon¹⁵ reports a study of an epidemic in the Yakima Valley of Washington during the summer of 1940. Howitt ran neutralization tests with sera from fifty patients; fourteen (28

per cent) neutralized the western strain of virus only, eight (16 per cent) neutralized the St. Louis virus only, and twenty-eight (56 per cent) neutralized both viruses. In a control group consisting of sera from seventy-five people not having encephalitis three (4 per cent) neutralized the western strain of virus, nineteen (25.4 per cent) neutralized the St. Louis virus, two (2.7 per cent) neutralized both viruses and fifty-one (67.9 per cent) did not neutralize either virus. Hammon believes that the clinical, epidemiological and laboratory evidence points to the presence of both viruses during the epidemic and that some of the patients probably had mixed infections.

Howitt had previously reported similar results in her study of California cases. At that time there was much migrant labor from areas where the St. Louis type of encephalitis had been prevalent and the St. Louis antibodies present were thought to represent previous exposure.

The epidemiology of encephalitis due to the equine type of virus is not entirely clear at present. Contact infection does not occur among laboratory animals nor did it occur in Record and Vawters³⁴ experiment where sick horses were placed in a corral with well horses. No cases are reported of attendants of patients becoming sick. There are two reports of infections among laboratory workers and statements that others have occurred.^{10, 18} In one case the route of infection is not definitely known; in another the person was heavily sprayed with a highly concentrated virus preparation. The disappearance of the disease in horses with the onset of frost early suggested the possibility of insect vectors. Ten varieties of *aedes* mosquitoes have been known to be able to transmit the disease under experimental conditions; eight the western strain and seven the eastern strain. Five varieties able to transmit the western strain are found in Minnesota.^{6, 28} No *aedes* mosquitoes have been found infected under natural conditions but recently Hammon¹⁷ has reported the isolation of the western virus from a lot of *Culex tarsalis* mosquitoes caught in the state of Washington. To date, *culex* and *anopheline* mosquitoes have not been shown able to transmit the disease experimentally. The tick, *Dermacentor andersoni*, is able to transmit the western strain of virus under laboratory conditions but no infected tick has been found in nature.²⁹ This is not a Minnesota tick. Recently it has

been reported that one of the conenose bugs, *Triatoma sanguisuga* Le Conte has been found infected with the western strain of virus under natural conditions in Kansas and is able to transmit infection to the guinea pig in the laboratory.²² This bug has not been found in this area. The reservoir of infection is at present not known. TenBroeck has suggested that birds would be a more likely reservoir than the horse. The eastern strain of virus has been isolated from pheasants and pigeons,^{1,8,32,33} and the western strain from a prairie chicken.³ TenBroeck³⁰ showed that blood sera of a turkey and some chickens from an area where the disease occurred in horses had protective power against the eastern strain. Howitt²¹ demonstrated antibodies against the western virus in chicken sera and a quail serum but she also stated that she had tested blood of chickens raised under such conditions that contact with the virus was not possible and demonstrated neutralization of the western virus so that protection by chicken sera may not always indicate previous infection.

The host susceptibility of both strains of virus is very wide. Some of the animals in which the western strain of virus has produced disease by various routes of inoculation are: the guinea pig, rat, mouse, rabbit, monkey, pigeon, calf, goat, duck, gopher (*Citellus richardsonii*), vole, burrowing owl, guinea fowl, gamble and English sparrow, quail, junco, thrasher, wild rats (cotton, kangaroo and wood rat), various species of wild mice, puppies, young turkeys and chicks.²¹ Most of these and others resistant to inoculation with the western virus have been shown susceptible to inoculation with the eastern type. The western strain of virus has been isolated from the brain of a deer.³ Some evidence of natural infection of the gopher (*Citellus richardsonii*) with the western virus has been presented by Gwatkin.¹⁴ In addition to looking for virus, Hammon⁶ has examined blood sera from a wide variety of animals and found antibodies against the western virus in the serum of the cow, dog, goat, horse, pig, sheep, field mouse, white-footed mouse, weasel, chicken, domestic mallard duck, Peking duck, domestic goose, great horned owl, domestic pigeon, turkey, red shafted flicker, sparrow hawk, killdeer, ring-necked pheasant, California quail and robin; 32.4 per cent of seventy-four domestic, and 5.1 per cent of seventy-eight wild animals had protection. He suggested barnyards and fowl runs as possible sources of infection. While

vector and reservoir have not been established under natural conditions the epidemiology of the disease is most readily explained by the assumption of an insect vector (or vectors) and a host (or hosts). At present it is not clear how the virus gets through the winter months, since a chronic carrier state has not been demonstrated in any animal. We have no evidence of infection in any native tick in this area that might carry infection through the winter. It has been suggested that migratory birds might be a reservoir of infection. As yet it has not been possible to fit in the distribution of the disease in man with any known migratory path.

Minnesota's Experience with the Disease (1938)

In 1938 an extensive epizootic of equine encephalomyelitis again occurred in Minnesota; 23,686 horses were reported as affected. During that year forty-seven human cases of encephalitis were reported to the Minnesota Department of Health. The onset in thirty-six of these cases was between August 13 and September 20, a period during which infection with the equine virus might be expected. Sera were tested for neutralization of the western virus in twenty-one instances;* fourteen sera neutralized the western strain of virus. Two sera neutralized the St. Louis virus and one additional serum showed moderate protection after two years' standing in the ice box. Only the sera showing no neutralization of the western virus were run with the St. Louis virus so we have no data comparable to Hammon's. The distribution of the cases with neutralization of the western virus was predominately rural; ten lived on farms, three in small towns, and one in St. Paul. Six cases occurred in a rural area with a radius of about ten miles. Two cases had close contact with sick horses. In the others there is no history of any contact with sick horses. No individual had contact with any other case. There were eleven males and three females. The ages varied from one month to sixty-six years, two in the first decade, one in the second, four in the fourth, one in the fifth, three in the sixth, and three in the seventh.

*Most of these sera were run by the following: Dr. Carl TenBroeck of the Princeton Branch of the Rockefeller Institute, Webster and Wright of the Rockefeller Institute, or Dr. Charles Armstrong of the National Institute of Health. A few sera were run in the laboratories of the Minnesota Department of Health.

Clinical picture: In the typical case, onset was rather sudden with headache and fever. In a day or two drowsiness appeared and in the mild case no further symptoms appeared. In the more severe case drowsiness progressed to stupor, at times alternating with marked restlessness. The sensorium became cloudy and there was disorientation in all fields. In about a week the temperature usually began to drop and a few days later the patient's condition began to improve. On physical examination stiff neck and less frequently tremors were practically the only physical findings.

The symptoms at onset in thirteen positive cases were: headache 10; nausea 3; chills 3; vomiting 2; malaise 4; dizziness 2; drowsiness 2; stiff neck 1.

During the course of the illness, eight of the patients were either drowsy or lethargic; seven complained of headache; six were said to be irrational. Diplopia and photophobia were each complained of by two patients. The acute phase of the illness lasted two to three weeks. The majority of patients had a complete amnesia for the period of their severe illness. The period of acute illness was followed in most cases by severe weakness, (ten of thirteen cases).

The physical findings were: fever 13 (103°-105° maximum); stiff neck 7 (moderate degree); tremor 4 (facial and hands); Babinski 1 (unilateral).

Examination of the spinal fluid showed an increase of cells in every case. The counts ranged between thirty and 400 cells. A differential count was done in nine cases: in seven there was a predominance of lymphocytes, in two a predominance of polymorphonuclear cells. Pressure determinations, quantitative protein and sugar studies were not done frequently enough to justify special comment.

The fourteenth positive case has been reported in detail by Dr. R. V. Platou.²⁸ A one-month-old child had a ten-day febrile illness in August and about one month later was noted to be developing symptoms suggestive of Little's disease.

The history of a well-studied case follows.

Case History

A.M., a man, aged fifty-six, onset afternoon August 17, 1938, with nausea, dizziness and drowsiness. The dizziness and nausea persisted the next day. The patient stayed in bed, was restless, tossed from side to side; that evening light stupor occurred, temperature slightly elevated. On August 19 temperature 104°.

At times patient was restless and delirious, at other times he was stuporous and could not be roused. He did not recognize his family. August 20 stupor alternated with restlessness; temperature 104°. The periods of stupor and restlessness continued until admission to the University Hospital August 23. Just before admission patient appeared somewhat better and recognized his family.

Physical examination: Upon admission August 23 the patient was difficult to arouse; T. 101 (R), P. 100, R. 24, B.P. 200/110. There were fine scattered rales over the lung bases. Heart was enlarged. No positive neurological findings. August 24, spinal puncture; pressure 12 mm. mercury—Queckenstedt normal. There were 81 cells, of which 61 were polymorphonuclears and 20 mononuclears; protein 114 mg., sugar 104 mg. On August 25, spinal puncture, 99 cells, 70 pmn., 29 mono. On September 7 cell count 0, protein 40.1 mg. w.b.c.: August 24, 14,080; August 6, 10,000. Course in hospital: Temperature dropped from 101 to 100° on August 26; stayed at this level until August 31 when dropped to nearly normal. Was restless and semi-conscious first 2 days in hospital, then gradually less restless and slept better; incontinent first six days in hospital. Discharged August 15 with weakness as only complaint. Contacts: patient treated a sick horse from August 1 to August 11. Was not off farm for two weeks prior to the onset of his illness. Before that, his only trips were to a neighboring town for supplies. He had no contact with any sick person.

Symptoms Reported by Others

Howitt²⁰ has listed the main symptoms in thirty-one California cases where the sera neutralized the western strain of virus or where this virus was isolated. In order of frequency the chief symptoms were headache, drowsiness, fever, vomiting, stiff neck and lethargy. Other symptoms such as muscle spasms, convulsions, irritability, rigidity of extremities and dizziness occurred less frequently. Gareau¹² in his clinical study listed high temperature, headache, malaise, pains and aches, and mental sluggishness as the main symptoms. He especially stressed headache. Nausea, vomiting and anorexia were also common. Neck rigidity and Kernig's sign were usually demonstrable. Nystagmus, difficulty in swallowing and speaking, convulsions, muscular twitchings and tremors occasionally occurred.

Breslich, Rowe and Lehman² in their North Dakota study mention severe headache, fever, general muscular pains, backache, nausea and vomiting, dizziness and drowsiness. More severe cases progressed to delirium and coma. Stiff neck was the most common physical finding. Coarse intention tremors of the face and loss of abdominal reflexes were quite common. The Kernig sign was present less frequently.

The mortality is difficult to determine. In Minnesota diagnosis was not established by laboratory methods in any fatal case. Of the thirty-nine cases occurring between August 13 and September 20, five died. In Minnesota in 1937, of six quite definite clinical cases in one locality, two died. Gareau reports four deaths among twenty-nine clinical cases. Howitt, two of thirty-one cases, and the North Dakota investigators five of twenty-three cases.

Sequelæ appear to be rather uncommon. In Minnesota in only one reported case has it been recognized—the infant who developed the clinical picture of Little's disease. Davis has reported sequelæ in two children in California.⁵ Both had marked mental retardation and in addition one had some paralysis and the other blindness and deafness.

Gareau at the end of two years knew of five cases: three children with various types of paralysis and still showing improvement; two adults, one with disseminated sclerosis, the other had mental confusion and dizziness.

The patients in this study with sera neutralizing the Saint Louis virus did not differ clinically from those with sera neutralizing the western strain of virus. Of the Saint Louis type, two cases occurred in a rural area and one in Saint Paul.

Summary

Fourteen cases of encephalitis with neutralization of the western strain of equine encephalomyelitis virus are reported. The epidemiologic and clinical features are briefly described.

METASTATIC BRAIN ABSCESES

GEORGE N. RUHBERG, M.D.

Assistant Clinical Professor of Nervous and Mental Diseases
University of Minnesota Medical School

Saint Paul, Minnesota

ABSCESES of the brain arising from a distant and seemingly unrelated focus often and unexpectedly presents a problem, difficult from a diagnostic aspect, deadly in its outcome and incomprehensible in its genesis.

Purulent disease of the bronchi and pulmonary tissue were recognized by Virchow, Gull, and others of that generation, as the chief causes of metastatic cerebral abscesses. This relationship still remains a curious phenomenon. In pyemia the brain seems more resistant to infection and formation of abscesses than other organs. This is well illustrated in their relative infrequency in ulcerative endocarditis. Shorstein thought that while possibly the brain had greater resistance to infective emboli in acute infections, its resistance in chronic cases was relatively weaker because of feeble production of antibodies compared with other organs. Pilot concluded the putrid abscesses usually found were due to a mixed infection of anaerobic organisms and streptococci and for their production it seemed necessary to have intermediate advanced lesions due to the same organism. These bacteria, particularly, develop in large numbers in the lung and have access to large vessels where thrombi are formed and carried by the blood stream to the brain. He thought the brain to be a good culture medium for these bacteria. Eagleton believed these brain abscesses were of venous origin and this explained the greater incidence of pulmonary antecedents over arterial-borne infections in ulcerative endocarditis. He also has shown that metastatic abscesses from ear and nasal sources do occur. Arnold found, experimentally, that the venous circulation from the head toward the heart is reversed when a positive intrathoracic pressure is encountered. Gardner surmised that coughing or straining, by causing this pressure, induced venous engorgement and arterial ischemia, thereby rendering the lodgment of an embolus easier and temporarily lowering the normal resistance of the cerebral tissue. It is significant that this close, or possibly closer, relationship between lung and brain is present in carcinoma of the lung. It seems paradoxical that

metastatic brain abscesses are rare in pulmonary tuberculosis. In short, the problem still remains unsolved.

Of the diseases of the lung associated with brain abscesses bronchiectasis is the main antecedent. In sixty-three cases of bronchiectasis, cited by Shorstein, the cause of death was bronchopneumonia in seventeen and brain abscess in thirteen. Apart from bronchopneumonia, brain abscess was more than twice as frequent as any other cause of death. Empyema was a far removed second to bronchiectasis. It occurred in cases where chest operations had or had not been performed. It seems clear that these operations bore no relationship to brain abscess formation. Gangrene of the lung was frequently cited. Nähter found purulent foci in the brain in eight out of 100 cases of pulmonary gangrene. This high percentage was not borne out in English and American series. Pulmonary tuberculosis, as already mentioned, was rare. Shorstein collected three cases, Claytor five and Parker one.

It has been pointed out that the division of bronchiectasis, lung abscess and empyema as separate antecedents is artificial. One may be instrumental in causing the other. All three are commonly present simultaneously, and there is always such a close relationship that it is reasonable to group them together. Other conditions mentioned are acute pneumonia, emphysema and bronchitis, the latter two being thought to be a coincidence. Claytor and Shorstein series are shown in Table I.

The cases here reported are from the services at the Ancker Hospital from the period 1924 to 1940. For comparative reasons all cerebral abscesses are listed. Their original source is shown in Table II.

A striking feature of this series is the number of pulmonary cases compared to those derived from the ear. This is at variance with the usual finding. For instance, Evans found 109 ear cases to forty-six pulmonary out of 194 cerebral abscesses. Weil estimated that 40 per cent were caused by otitis media. Practically all authors

found pulmonary states second in frequency to ear conditions.

The distribution of the pulmonary cases is shown in Table III.

One case of lung abscess, in a young man with brain abscess, is not reported on account of lack of autopsy findings. One patient with lung abscess had pyemia, but is included in this group on account of the original condition of aspiration pneumonia and lung abscess. This group is subdivided into: (1) acute and (2) chronic—basing this division on the pulmonary condition. The acute cases are six in number: three bronchopneumonia, one miliary tuberculosis, one aspiration pneumonia with lung abscess and pyemia, and one congenital heart with pneumonia. The six chronic cases are: three bronchiectasis, two lung abscesses and one empyema.

An example of the chronic group is the following.

Case 5.—A white man, aged sixty, was admitted to the hospital February 3, 1936. He had been in rather poor health the past few years and he had had a chronic cough for four years. Three years ago he had had an actual hemorrhage and had had more hemoptysis lately. He was hospitalized in 1935 for six weeks on account of what was thought to be unresolved pneumonia. It was suspected at that time he might have a carcinoma of the lung.

The present illness began suddenly two weeks previous to admission with a chill which lasted almost three hours, followed by sweating. He seemed to be all right, except for loss of appetite, until January 30, 1936, when he had another chill and complained of pain

throughout his entire body. The next day he was unable to speak, had respiratory difficulty and was unable to swallow. The following day he regained his ability to speak and was apparently better, but he complained of a headache. The following day, February 2, 1936, he became quite weak and complained of more headache and difficulty in swallowing, and he vomited. The morning of February 3 he was about the same until noon, when he complained of a stiff neck and that afternoon he became delirious and saw things on the wall. He was stuporous at times. He was hospitalized at 8 p.m., February 3, 1936, and died twenty-four hours later.

This is rather typical of the chronic group. It is a history of years of chronic lung trouble which is suddenly overshadowed by symptoms of sepsis of the nervous system coming on suddenly, although somewhat gradual at first. Once established it rapidly progressed to death. The following is an example of a brain abscess following an acute pulmonary disease.

Case 4.—A white girl of six, who had been a "blue baby" and had shown signs of heart disease since birth, was admitted to the Receiving Room of the

Ancker Hospital, January 17, 1936. She died ten minutes later. A cursory examination revealed a stiff neck, marked clubbing of the fingers and cyanosis. She had been sick for one week from signs of an upper respiratory infection and had complained of pain in the legs.

the acute cases was 7.5 days. Of the chronic group one was ill nine years; the shortest six months, the average being four years. There were eight males and four females. Ages ranged

TABLE IV.

Case	Clinical Course of Neurological Complications	Duration	Post-mortem Report
1.	Fever, irritability, twitching left side, neck rigidity, drowsiness, convulsions, left hemiparesis, choked discs, stupor, purulent spinal fluid	28 days	Multiple abscesses in occipital right parietal and left temporal lobes—ruptured.
2.	Headache, fever, drowsiness, stupor, delirium, rigidity of neck, purulent spinal fluid	4 days	Multiple abscesses in left frontal temporal and occipital lobes—ruptured
3.	Drowsiness, fever, weakness, pain in neck, headaches, vomiting, stupor, Kernig, Babinski, purulent spinal fluid	8 days	Abscess right frontal lobe—ruptured
4.	Fever, headache, rigid neck, stuporous, purulent spinal fluid	7 days	Multiple abscesses in right occipital lobe.
5.	Chills, aphasia, headache, vomiting, neck rigidity, stupor, purulent spinal fluid	5 days	Abscess in left parietal lobe.
6.	Headache, fever, drowsiness, stiff neck, stuporous, purulent spinal fluid	4 days	Multiple abscesses in both occipital lobes—ruptured.
7.	Headache, weakness, fever, drowsiness, weakness left side, delirium, rigid neck, slow respiration, strabismus, left hemiparalysis, purulent spinal fluid	11 days	Multiple abscesses in pons and cerebral peduncle on right.
8.	Muttering delirium (picked up by police), stiff neck, fever, stupor, purulent spinal fluid	10 days	Multiple abscesses in occipital lobes, both temporal and parietal lobes, greater on left than right.
9.	Vomiting, headache, rigid neck, restless, semicoma, unconscious, purulent spinal fluid	4 days	Multiple abscesses, bilateral.
10.	Headache, fever, paresis left arm, right ptosis, drowsiness, hiccough, semicoma, spinal cells 342	8 days	Multiple abscesses.
11.	Convulsions, fever, drowsiness, rigidity of neck, purulent spinal fluid	3 days	Multiple abscesses.
12.	Chills, fever, listless, confused, stuporous	10 days	Multiple abscesses.

Post-mortem revealed a patent interventricular septum, brain abscess, pulmonary stenosis and meningitis. A culture from the meninges showed the presence of *Bacillus coli*. *Staphylococcus albus* (non hemolytic) and *Streptococcus hemolyticus* in small numbers.

The frequency of association between congenital heart disease and brain abscess has been commented on by Gowers, Shorstein and Parker. Secondary change in the lung and short circuiting of the circulation were believed factors in producing this association.

The average duration of the primary disease in

in all decades from thirteen months to sixty years, the acute group being the younger. In the following table are arranged the twelve cases. The sequence of neurological symptoms as they arose, their duration and post-mortem report are recorded in Table IV.

The general symptoms of the pulmonary group were no different from those of brain abscesses from other sources. They were headache, fever, rigidity of the neck, increase of cells in the spinal fluid (or purulent fluid), leukocytosis, drowsiness, delirium, stupor, unconscious-

ness. The initial symptom was usually headache, although chills, convulsions, vomiting or drowsiness were also noted.

The progress of symptoms after once starting was rapid. It made little difference whether the pulmonary condition was acute or chronic. The duration of the symptoms of abscess in the acute was nine and a half days and that of the chronic seven days. Of the entire group only one was in the hospital for treatment of the pulmonary condition. At the time of admittance to the hospital three were delirious, one stuporous, one unconscious and two died in the Receiving Room. There were localized findings in three cases. The remainder had only general symptoms of a purulent meningitis. Of the chronic pulmonary group four had multiple abscesses and two had single. This corresponds somewhat with larger series having up to 46 per cent single ones. The entire acute pulmonary group had multiple abscesses. The distribution favored no particular lobe or side of the brain. As expected there were no cerebellar involvements.

It is instantly apparent that the entire acute group were doomed on account of the multiplicity of abscesses. In the chronic group two were single. One of these presented some localizing symptoms. Unfortunately both had ruptured abscesses and purulent meningitis on admittance. However, every case is a law unto itself and no sweeping statement is justified. Some fundamental factors that must be considered in dealing with a patient of this group are: (1) the 50 per cent or less possibility of the abscess being single; (2) the general condition of the patient as to ability to stand surgery; (3) the presence of localizing symptoms; (4) the primary disease. Cases successfully treated are recorded. Our attitude should be of an open mind, fully realizing the odds against survival, but when the situation warrants, the opportunity should be grasped and risks, although heavy, should be taken.

The second group found in this series was composed of cases associated with ulcerative endocarditis. In acute fulminating pyemia the brain, as already mentioned, is rarely affected. In the protracted complicated illness of chronic cases the brain, along with other organs, suffers from the deposition of purulent emboli and brain abscesses may result. The outlook after this event is practically hopeless, the main interest being pathological rather than clinical. When brain

abscess develops, these patients die, because it is the last and most lethal of a series of complications which in themselves would ultimately prove fatal. Three patients constituted this group; two had infarcts of brain, spleen, kidney as well as brain abscesses. Their illness was prolonged and complicated. The third was somewhat different in that no infarcts were found except one in the brain.

Case 13.—A white woman of forty-four suddenly developed pain in the right lower quadrant. Two days later she developed chills and high fever. The chills continued intermittently for three weeks. She then entered Ancker Hospital in a weak, listless, anemic condition. A blood culture of *B. coli* was found on six different occasions. She had occasional chills and her temperature ranged from 99 to 105. A few superficial abscesses were found to contain *B. coli*. She improved under sulfanilamide until approximately two months after the onset of her illness, when she suddenly developed a chilly sensation of the left side which was superseded by a left hemiplegia and some loss of sensation. She regained some of her sensation, but in a few days had a relapse and died.

The autopsy diagnosis was: septicemia, abscess in the right parietal lobe surrounded by an area of softening, acute and chronic pyelonephritis, ureteral stone, and acute splenitis. The sequence of events was apparently pyelonephritis, endocarditis, septicemia, brain infarction and abscesses.

The third group of cases is that associated with suppurative processes which had subsided in three instances and improved in one. In some the original condition had healed so long ago that no casual connection was immediately suspected. An example is:

Case 15.—A white child, of seven months, developed an infection of the face two weeks after birth. Following this an ulcer of the left leg appeared and healed in four weeks. Within a month jerking of the right arm appeared and ceased under calcium therapy. It reappeared in another month and again ceased. There was then a definite latent period until three weeks prior to admittance, when the child seemed ill, had a stiff neck and a large head was noted.

On admittance an enlarged head, dilation of the veins of the scalp, tense fontanel, slight rigidity of the neck, slight fever, leukocytosis and 1,711 cells in the spinal fluid were noted. During the next five weeks the cell count diminished, a diagnosis of left frontal abscess was made by aspiration, a craniotomy performed, and the abscess drained.

Table V briefly describes the original infection, clinical course of cerebral symptoms, and findings on autopsy or operation:

METASTATIC BRAIN ABSCESES—RUHBERG

The characteristics of this group, besides the lengthened interval between the original infection and cerebral involvement, is the slow development of symptoms compared with the pulmonary group at the age of three, undoubtedly had a skull injury and a possible osteomyelitis from falling on a pair of scissors. This assumption seems justified by the appearance of two spicula of bone up

TABLE V. METASTATIC ABSCESS OF BRAIN SECONDARY TO INFECTION THAT HAD SUBSIDED OR IMPROVED

Case	Original Infection	Duration of Illness	Clinical Course of Cerebral Complications	Duration before Death	Autopsy or Operation
13.	Ulcer of leg 4 plus Wassermann Paresis	1 month	Numbness and paresis of left hand. Jacksonian attacks, left side, beginning in hand. Cerebration slow, drowsiness, stupor.	48 days	Walled off abscess in right parietal lobe. 4.5 cm. in diameter. Softening around abscess.
14.	Osteomyelitis left leg—right shoulder in 1928 and right thigh in 1931. Well until 1939.	3 years	Headaches for three weeks. Pain in neck three days. Slight neck rigidity. Right knee and ankle jerk greater than left. Babinski (?) on right, stupor, purulent spinal fluid. Coma.	4 weeks	Large abscess in left occipital lobe, ruptured into ventricle. Osteomyelitis of occipital bone.
15.	Infection of face Ulcer of leg.	4 weeks	Jerking movements right arm for two weeks following infection. Ceased and returned one month later and ceased under calcium therapy. Two months later malaise, stiff neck, large head. Spinal cells 1711.	4 months	Craniotomy. Very large abscess in left frontal region.
16.	Age three—stab wound of scalp, infection, osteomyelitis. Well 19 years. Age twenty-two—acute respiratory infection, five days. Temperature 102.	Scalp 3 weeks healed 3 spicules of sequestra appeared until age twelve. Respiratory infection five days.	Headache one week after respiratory infection. Vomiting, fever, drowsiness, lethargy, stiff neck, weakness in left arm and leg. Spinal cells 450. Deepening coma.		Craniotomy two months after onset. Pocket of yellow fluid—large abscess chained. Culture <i>Staphylococcus hemolyticus</i> .

and the finding of single abscesses and localizing signs in three of the four. In Case 14 there probably is a justifiable objection to the diagnosis of a metastatic abscess on account of the osteomyelitis of the occipital bone. However, the two appearing synchronously after an interval of eight years and the element of metastasis being present in one lesion, and possibly in both, justified, I believe, its inclusion in this group. In Case 16, the nineteen year interval between cranial injury and formation of brain abscess presents an intriguing problem between cause and effect. This patient,

to the age of twelve. At operation the aspiration of yellow fluid from within the brain substance, followed by aspiration of an abscess, suggests the presence of both a cyst and an abscess. The connection between her acute infection and abscess formation recalls Weed's experiments in producing brain abscesses. He found that introduction of pyemic organisms into the blood stream only on rare occasions produced an abscess, but that after injury of the brain they could be produced regularly in this manner. In Case 16 it is probable that similar mechanisms were in-

volved, viz.: local injury, cyst formation, reduced local resistance, acute infection, metastasis and abscess formation. On x-ray and at operation no sign of osteomyelitis or meningeal adhesions was found. In Case 14, x-ray studies would probably have helped the localization.

Summary and Conclusion

From a clinical study of nineteen cases of metastatic brain abscesses we draw the following conclusions:

1. The prognosis is mainly dependent on the acuteness and severity of the primary infection.

It was hopeless in the acute pulmonary and endocarditis groups of this series.

2. In the chronic pulmonary group, although no favorable cases were present, single abscesses were found in 33 per cent. The possibility of favorable surgical intervention in an occasional case is mentioned. The rapidity of progress of the cerebral complications seems characteristic.

3. In Group 3, the marked interval between the original infection and abscess formation, the comparative slowness in development, and the finding of single abscess, seem to make this group, from a prognostic standpoint, favorable.

THE ADVANTAGES AND LIMITATIONS OF CERTAIN PRACTICAL ADJUNCTS IN THE DIAGNOSIS OF DISEASES OF THE HEART

FREDRICK A. WILLIUS, M.D.
Rochester, Minnesota

FOR thorough appraisal of the cardiovascular system the physician first utilizes the advantages of a carefully elicited history, which is then supplemented by complete physical examination of the patient. In using the expression, "complete physical examination," I do not mean an examination of the thorax, but a complete examination of the entire body. Limited examinations for apparently local complaints are to be condemned as inconclusive, treacherous, and of extremely doubtful value to both the patient and the physician. In the daily practice of medicine the physician who adheres strictly to the routine of complete and thorough examination repeatedly discovers evidence of disease entirely unrelated to the patient's presenting complaint, and frequently the patient has been completely unaware of its existence. Such unexpected revelations may comprise conditions of serious or potentially serious consequences which may be amenable to surgical removal and cure, whereas failure to recognize them at an early date likely would lead to disastrous eventualities.

It is not my intention to deal extensively with the methods of physical diagnosis in this discussion, for it must be assumed that every physician is well grounded in this subject and is thoroughly imbued with the knowledge that this approach to

a diagnostic problem must necessarily supersede all other methods of clinical detection. However, with the advent of ever increasing diagnostic adjuncts, both laboratory and bedside, the tendency is developing in the medical profession to employ such methods at the expense of physical diagnosis. Progress in any field of endeavor results in a constant addition of new facts, methods, and apparatus which may result in a maze of confusion unless the individual physician has more than a casual acquaintance with the newer knowledge pertaining to disease.

The patient suffering from heart disease, and especially the patient in whom heart disease is suspected to exist, frequently has become the pathetic victim of mechanistic diagnosis. The tendency exists today for hurried questioning of the patient, followed by a rather cursory and limited physical examination, and then profound emphasis is accorded instrumental methods of examination, motivated by the hope that an instrumental method will provide the answer in one way or another. This prostitution of modern medicine is lamentable because it fails to carry out the physician's obligation to the patient and greatly devaluates the merits of the diagnostic adjunct in question.

An accessory method of diagnosis should never be employed with the idea of superseding of careful history-taking and thorough physical ex-

From the Section on Cardiology, Mayo Clinic, Rochester, Minnesota.

amination. The various accessory methods must always be supplemental, and it is extremely important that the clinician who uses such special methods thoroughly acquaint himself with both their advantages and limitations and their ever changing order of importance from case to case.

I shall not attempt to discuss all the adjunct methods of cardiac diagnosis, but rather limit myself to those that are now directly or indirectly available to all physicians. Even though the physician may not be equipped to perform roentgenographic or electrocardiographic examination, he must acquire the knowledge necessary to interpret the results of the examinations and to correlate intelligently the findings with the complaints and the physical observations concerning the patient involved. To accept the purely technical report of a laboratory or of another physician on such isolated evidence is unsound and fraught with great danger; unless the physician who refers his patient for special study of such a character is able to interpret the resultant findings and apply them to his special problem in an understanding manner, he would be safer in relying wholly on his own observations as derived from careful physical examination.

Roentgenography

Roentgenography is a simple method to determine the size, shape, and position of the silhouette of the heart and aorta. However, certain facts regarding the variations in its technical application must be realized. For the prompt and accurate determination of the size and contour of the cardiac silhouette the teleroentgenogram is very satisfactory. In this method the corrected distance of the roentgenogram from the tube has been determined, which results in minimal distortion of the size of the silhouette. For practical purposes the extension of the silhouette to the right of the midsternum is added to the corresponding extension from the midsternum to the left border of the silhouette. This value is then compared to the transverse internal diameter of the bony thorax. Normally, the total transverse diameter of the cardiac silhouette is roughly less than 50 per cent of the internal diameter of the thorax.

However, certain variables enter into the interpretation of the cardiac silhouette, and unless they are appreciated serious errors may occur. When the diseased heart or the heart suspected

of being impaired is being dealt with, it is always extremely important to ascertain whether or not the heart is enlarged. The enlarged heart, with rare exceptions, is structurally impaired, although the reverse of this statement emphatically is not true. The roentgenographic silhouette of the heart is greatly influenced by the habitus of the patient and these variations must be thoroughly appraised when judgment is expressed on the interpretation of the size of the heart.

In the tall asthenic type of bodily build, the longitudinal diameter of the thorax is lengthened and further increased by a relatively low diaphragmatic level. Under these circumstances the cardiac silhouette frequently is centrally situated, elongated and narrow, and on casual inspection gives the impression of a heart presumed to be smaller than the average normal heart. Such silhouettes may be considerably less than 50 per cent of the internal transverse diameter of the thorax in size and yet represent abnormal enlargement of the heart. It is necessary, under these conditions, to appraise carefully the contour of the silhouette, seeking abnormal prominences of the regions of the individual chambers of the heart, alterations in the shadow of the visible aorta, and, particularly, prominence of the conus arteriosus, the region in which the pulmonary artery joins the right ventricle. A prominent conus arteriosus commonly is present in mitral stenosis, even in the presence of an otherwise normally sized cardiac silhouette. It also occurs in various types of congenital cardiac defects.

In the short, stocky and overweight patient the exact reversal of these conditions exists. The thorax is diminished in its longitudinal diameter, the diaphragm is situated at a rather high level and the lateral diameter of the thorax commonly is increased. This status results in a cardiac silhouette that is broadened in its lateral diameter and shortened in its longitudinal diameter, and it appears to be pushed up by the high level of the diaphragm. Such a silhouette not uncommonly is interpreted as significant of an enlarged heart, whereas actual measurement and correlation of the cardiothoracic ratio reveal the contrary. In this connection the well-established fact should not be forgotten that within physiologic limits the weight of the heart parallels the weight of the body. In extreme obesity, the physiologic limits

may be rapidly supplanted by pathologic limits. Pericardial adhesions and calcification of the pericardium are not uncommonly demonstrated.

Lateral and oblique views of the heart at times give valuable additional information, but surely do not fall into the category of routine procedures. This is likewise true of roentgenograms of the esophagus, which at times are of distinct value, particularly in the detailed study of the auricles.

Roentgenography is an extremely valuable supplemental method of cardiac diagnosis, but its value obviously rests on an understanding of its advantages under one set of circumstances and of its limitations under another. It is a method that today is available to virtually all physicians, and its full utilization is urged with the reservation that the interpretation of its results be applied in an intelligent manner.

Roentgenoscopy

Roentgenoscopy is of definite value under certain circumstances, but certainly should not supplant teleroentgenography as a routine procedure. It is obviously valuable in observation of the beating heart, permits the recognition of abnormal pulsations and of fixation of certain regions of the organ and enables the examiner to determine the pulsation of regions of increased density which may or may not be proved to represent dilatation or aneurysm of the aorta. Special attention to the valvular regions usually permits identification of calcium deposits when they are present in the valvular leaflets and rings, notably in the aortic valve. Cardiac infarcts, particularly when they are situated near the apex of the heart or are encroaching on its lateral border, will be detectable by a region of systolic expansion, instead of the normal recession. Extensive thinning of the left ventricle, the so-called ventricular aneurysm, consequent to a large myocardial infarct, may be visible clearly as a bulge in the cardiac silhouette.

Electrocardiography

Electrocardiography now has been accorded widespread use so that the patient frequently demands that a record be taken. The layman cannot be expected to have sound judgment in this matter because he is inclined to view this clinical adjunct as a method that never fails to inscribe the answer as to whether the heart is normal or impaired, and, if impaired, how seriously. Un-

fortunately, this lay philosophy has become disseminated in an alarming manner among physicians, and a method of precision is being unwisely applied and its observations are being badly interpreted.

The electrocardiogram is the graphic inscription of the electrical activity of the heart, and it must be made under prescribed and universally accepted methods of standardization. Electrocardiography is a delicate method of registration, and one which is subject to certain environmental variables and definitely to physiologic variables in the individual patient, even when the heart is perfectly normal. As in the case of the teleroentgenogram, the habitus of the patient somewhat influences the basic characteristics of his electrocardiogram. Changes in posture invariably result in minor variations in the resulting electrocardiograms, so that the physician must be aware of these physiologic variations if he is to avoid error. He must not accord importance to minor variations in two electrocardiograms, when one was recorded while the patient was sitting erect in a chair and the other was recorded with the patient in the recumbent posture.

The determination of a clear-cut electrocardiographic abnormality never should be the basis for final commitment, because the making of such a commitment is unwise and dangerous until judicious correlation of the findings of abnormality is made with the patient's clinical history, physical observations and other pertinent data. It is a great mistake for a physician to attempt to express a diagnostic opinion on the basis of the electrocardiogram alone. Nevertheless, this practice has become so universal that I fear the future of electrocardiography will be one of increasing uncertainty and confusion, rather than one of progressive certainty and clarity. A new order of specialist has been evolved, the so-called electrocardiographer. He has acquired an electrocardiograph and has learned enough of its technical secrets, invariably acquired through the help of a high-pressure salesman, to permit him to register reasonably good records. He then learns the basic principles of electrocardiographic interpretation, so that his trained eye reaches that stage of perfection whereby he is enabled at a glance to detect abnormalities. These are then recorded at the bottom of the folder. This could be an ideal point at which to stop, but such self-restraint usually is not forthcoming; instead, he

ponders a moment and then inscribes a clinical diagnosis for a patient with whom he has had only casual contact and whom he has not examined (because the patient was referred by another physician). The resulting clinical diagnosis may be either vague or definite. Numerous examples could be presented, but I am certain that I need mention only a few to verify the correctness of my contention. This electrocardiogram then, suggests "myocardial disease," "coronary disease a likelihood," "myocardial weakness," and even the prediction of "valvular disease" has been encountered.

Needless to state, this increasing perversion of a valuable method of diagnosis is lamentable. The so-called electrocardiographer has placed himself in an unenviable position: his procedure has removed him from the rank of a physician to that of a restricted technician. I am certain that this was not his original intention.

The physician who conscientiously desires to learn electrocardiography can readily do so, but I sincerely advise him to learn this science before he purchases an instrument. A few years ago the cost of electrocardiographic equipment precluded its widespread use, but now certain less expensive and certain cheap portable units have made the method available to many more physicians than formerly. Censure must not be limited to the medical profession alone, because unwarranted high-pressure salesmanship on the part of certain manufacturers has promoted this unfortunate situation. It has recently come to my attention that physicians who were contemplating the purchase of electrocardiographs frankly stated to salesmen that they were not familiar with the interpretation of electrocardiograms, only to be assured that for a nominal fee the records could be sent to the manufacturer for interpretation. Such conduct must not be tolerated by the medical profession, and it is only the individual physician who can alter this situation by his refusal to enter into such a ridiculous arrangement. He should critically examine various instruments before concluding to purchase one.

The electrocardiogram is the registration of antagonistic electrical effects which vary from instant to instant; they are antagonistic in a regional manner, as, for instance, between apex and base, anterior and posterior surfaces, right and left sides of the heart. The electrocardiogram

is influenced by innumerable alterations that may affect the muscle mass of the heart or isolated regions only; or combined alterations may exist circumstantially in such a manner that a perfectly normal record may be obtained of a seriously impaired organ.

During recent years, as the result of meticulously thorough studies based on careful clinical, electrocardiographic, and pathologic correlations, the term "electrocardiographic pattern" has come into general use. These studies have been signal contributions to electrocardiography, yet, like the science itself, have been misinterpreted and abused, and minor graphic alterations casually resembling the more characteristic findings frequently have been accepted as being genuine, when in reality they are counterfeit. For example, in many cases acute myocardial infarction inscribes a certain type of electrocardiogram that is well known and is peculiarly characteristic. However, in many other cases this is not true. It is in such instances, particularly, that the clinician must utilize his clinical sense to the utmost and not be misled by a record that does not reveal the conditions which he anticipated. More than one infarct occurring within a short period, infarction involving the interventricular septum, and pericarditis, may obliterate many of the characteristics of the classic pattern. Even when the classic pattern is existent, I demand the right to examine the patient before making a definite commitment.

Many other examples of a similar nature could be presented, but I am hopeful that my attitude in this matter has been clearly stated.

Circulation Time

Several simple methods have been devised for estimation of the time of circulation between two known points in the system. I shall limit my discussion to consideration of a satisfactory and simple method which can be performed in the office or at the bedside in a very short period, without any elaborate equipment. A 10 c.c. syringe and needle are all that are required. By the injection of 5 c.c. of sodium dehydrocholate (decholin) into the median basilic vein, the time of the transit of this substance to the tongue can be determined. The patient recognizes arrival of the substance at the tongue by a sudden, bitter, and very pungent taste which very promptly is lost. The instant the substance has been in-

jected is noted by the second hand of an ordinary watch or a stop watch, and is recorded; again, the instant the patient tastes the material (which he indicates by the declaration, "now") is noted. The normal time for this circuit to be made ranges from ten to sixteen seconds.

During the time it leaves the median basilic vein and until it is delivered to the arteries of the tongue, the substance reaches the right side of the heart, passes through the pulmonary circulation, reaches the left side of the heart and is disseminated into the systemic arterial circulation. Marked shortening of the circulation rate provides extremely valuable data referable to circulatory shunts, such as occur in patency of the interauricular and interventricular septa, and by means of which some of the material as well as some of the blood escapes the pulmonary circulation and passes immediately into the left side of the heart. Diminution of the circulatory rate to seven or eight seconds or less is significant.

In a contrary manner, prolongation of the circulation rate may occur, particularly in congestive heart failure when venous pressure is increased beyond normal. The value of the method in such circumstances is doubtful, owing to the fact that other obvious factors indicating a state of failure are present.

Conclusions

It thus is apparent that each clinical adjunct considered herein is of distinct value in the diagnosis of diseases of the heart, yet no single method is fruitful under all circumstances. Each has its advantages and limitations, which vary under different disease states and almost from patient to patient, and it therefore is imperative that the physician who utilizes these supplemental clinical procedures clearly recognize these facts, interpret the observations judiciously and wisely, and always correlate them with the patient's history and the observations made at careful physical examination.

RESULTS OF THE LOWMAN OPERATION FOR PARALYSIS OF THE ABDOMINAL MUSCLES

GEORGE A. WILLIAMSON, M.D., and JOHN H. MOE, M.D.

Saint Paul, Minnesota

and

W. COMPERE BASOM, M.D.

Rochester, Minnesota

LITTLE attention has been given to the loss of integrity of the abdominal musculature. In 1931, Lang¹ stated that an operative method for overcoming paralysis of the abdominal muscles, though desirable, had not been attempted so far as he knew.

Paralysis of the musculature of the abdominal wall is far more serious than has been previously appreciated and may interfere markedly with the harmonious function of the body as a whole. This was Lowman's³ viewpoint in 1931. He had observed patients who had poor locomotion which apparently was due to poor stability of the trunk on the pelvis. He also thought that there might be a specific relationship between abdominal paralysis and paralytic scoliosis.

The practical use of fascial transplants to repair structural defects has been well established, but Lowman was the first to devise a plan whereby a new insertion was provided for the remaining unparalyzed abdominal muscles by the use of fascial strips. He used this method in several cases² and found that it was possible and practical to recapture some of the lost power in the presence of partial paralysis of the abdominal muscles. He also found that stabilization of the trunk on the pelvis could be improved.⁴

Since 1933, thirty-one operative procedures of the Lowman type have been performed on twenty-nine patients at the Gillette State Hospital for Crippled Children. This procedure was used in cases in which the musculature of a portion or of all of the abdominal wall was weakened. Fascial strips were used to bridge the paralyzed region and thus to form a new point of insertion for

the remaining uninvolved muscles. Many patterns were formed by the fascia according to the distribution of abdominal paralysis. In all cases, the paralysis was due to poliomyelitis.

The strips were extended subcutaneously to each costal margin, usually to the seventh and eighth ribs in the midclavicular line (Fig. 2). This gave an additional new insertion for the unparalyzed

Fig. 1. Beevor's sign indicates paralysis of upper portion of rectus muscles.

Fig. 2. Fascia lata transplant for paralysis of the muscles of the upper part of the abdomen.

Fig. 3. Fascial transplant for paralysis of the muscles of the lower part of the abdomen.

In seven cases the umbilicus shifted downward with contraction of the abdominal muscles. Beevor's sign (Fig. 1) thus revealed that the upper portions of the rectus muscles were paralyzed. Fascia was obtained from the thigh in a rectangular piece. Throughout most of its length this was split into two or three strips as the condition indicated. The one end which was to be fixed around the umbilicus was left intact, however. Through a small skin incision, the fascia was placed around the umbilicus and sutured to the adjacent anterior sheath of the rectus muscle.

abdominal musculature. The muscles thus working through the fascia helped support the weakened part of the abdominal wall. In some cases two strips instead of one were used to each side.

In ten cases there was a paralysis of the lower abdominal muscles. The fascia was attached to the rectus sheath and muscle and around the umbilicus. A strip was extended subcutaneously to each anterior superior iliac spine (Fig. 3). In some of these cases a strip was also extended from the umbilicus to the symphysis pubis. A drill hole large enough to admit the strip of fascia was made in the region of each anterior superior spine. The end of the fascial strip was pulled through this hole, doubled back and sutured to itself with silk. The fascia to the symphysis pubis was extended inside the rectus sheath to the pubic bone where it was run through a slit and sutured to itself. In five of these cases only one strip of fascia was used to correct the paralysis of the lower abdominal muscles. The fascia pulled out in two of these cases and at another operation the fascia was extended to the anterior superior iliac spines.

Examination in six cases revealed that the umbilicus shifted laterally instead of vertically when the abdominal muscles were contracted. Beevor's sign thus indicated that the oblique and transverse abdominal muscles were paralyzed on one side. In these cases the fascia was an-

chored about the umbilicus as in the preceding cases. Then one strip was brought subcutaneously to the costal margin as far laterally as possible making as wide an angle as possible and

per quadrant was good. The remaining portion of the abdominal wall was unsupported (Fig. 6).

In four cases the muscles of the entire abdominal wall were paralyzed. In these, the fascia

directing the line of force more parallel to the fibers of the oblique muscles. The lower strip was taken through a subcutaneous tunnel, through a drill hole in the anterior superior spine of the ilium on the same paralyzed side. The fascia was sutured with silk (Fig. 4).

One patient had paralysis of the abdominal muscles in the left lower quadrant. In this case the umbilicus shifted upward and to the right. The fascial strips were attached to the umbilicus, and to the left anterior superior spine and through the sheath of the left rectus muscle to the pubis (Fig. 5).

In another case the musculature in the left up-

per quadrant was good. The remaining portion of the abdominal wall was unsupported (Fig. 6).

In June, 1941, when the follow-up study was made, the period which had elapsed after operation was from six to ten months in seven cases, one year in seven, two years in four, three years in four, five years in three and six years in four cases.

Results

Of the twenty-nine patients who were subjected to operation, twenty-eight were improved. All the patients who had paralysis of the entire

abdominal wall had difficulty in voiding and defecating. After the operation they were able to perform these acts comfortably and also they felt more secure.

It was noted that the fascial bands were at first small and string-like. Later, after training, these bands became strong, rope-like cords. Some patients, particularly those who had weakness of the upper part of the abdominal wall and had been unable to raise the head, could accomplish this easily after operation. Some of the patients eventually were able to rise unassisted to a sitting position.

The support given between the thoracic cage and pelvis decreased the lumbar lordosis in all the cases in which this deformity was present. Bulging of the abdominal wall was decreased. Only fourteen patients had to continue to wear support of some kind.

The most noticeable results in all the cases in which improvement resulted from operation were as follows: fatigue was lessened; the patients could stand and sit without tiring, and they were able to perform the acts of walking and sitting better; the gait was more stable; they could use their braces better. The support between the thoracic cage and pelvis enabled the patient to swing the legs better even when they were wearing braces.

Effect on scoliosis.—In twenty of these cases scoliosis was present at the time of the first examination. Additional treatment for this condi-

tion was necessary in every case. In nine of the cases there was no deformity of the spinal column before the operation. No deformity developed in any case afterward so far as was ascertained.

Summary and Conclusions

Thirty-one operations were performed on twenty-nine patients; the first operation in two cases was unsatisfactory and another operation was performed. Only one patient did not improve after operation.

This procedure was used primarily to reinforce the weakened abdominal wall and secondarily to aid in the prevention of scoliosis. Apparently it was a worth-while procedure from the standpoint of stabilizing the abdominal wall but was probably of no value in the prevention of scoliosis.

After reinforcement of the abdominal wall, sitting and walking can be performed better, the gait is improved even with the presence of braces on the extremities, fatigue is lessened, lumbar lordosis and bulging of the abdominal wall are decreased and control of the bladder and function of the bowel in cases of paralysis of the entire abdominal wall usually are improved.

THE DIAGNOSIS OF THE ACTIVITY OF PULMONARY TUBERCULOSIS

ROBERTS DAVIES, M.D.

Nopeming Sanatorium

Nopeming, Minnesota

THE determination of the activity or inactivity of a tuberculous lesion is a problem that frequently confronts the general practitioner and occurs occasionally in the practice of almost every specialist. It is a problem of importance because failure to appreciate activity may mean failure to forestall a long and disabling illness and even death. On the other hand, the misguided treat-

ment of an inactive lesion means loss of time and money to the patient and frequently the serious disruption of his life.

The concept of activity of a tuberculous lesion is purely clinical. An active lesion is one which is unstable and likely to increase. Conversely, an inactive lesion is one which is stable and unlikely to spread. The diagnosis of such a lesion by no means precludes the presence of living tubercle bacilli. Since such bacilli are always potentially

Presented to the Medical Staff of St. Luke's Hospital, Duluth, Minnesota, June 19, 1941.

dangerous, it follows that diagnosis of inactivity must be made with reservations.

In arriving at a judgment of activity, the local symptoms of the pulmonary disease, such as cough, expectoration, chest pain, and hemoptysis, are usually considered first. In a general way the more such symptoms are present and the greater their severity, the more likely it is that the lesion is active. However, the differential value of such local symptoms is not great because they are all frequently absent in the presence of active tuberculosis and may all be present, including hemoptysis, with a thoroughly stable and inactive lesion.

The general or toxic symptoms of tuberculosis, such as fever, sweats, tiredness, loss of appetite, and loss of weight, are of more value. In the presence of a tuberculous lesion and in the absence of any other cause, they constitute a rather dependable evidence of activity. The most important thing to remember about all symptoms, both local and general, is that their complete absence is compatible with active and progressive tuberculosis.

Physical findings should be mentioned rather for the sake of completeness than because they are helpful in the diagnosis of activity. Abnormal physical findings are frequently entirely absent in progressive tuberculosis and, conversely, extensive abnormal signs including numerous moist rales may be found over lesions that have been stable and inactive for years.

Laboratory findings are often valuable in making a diagnosis of activity. The presence of tubercle bacilli in smears made from plain or concentrated sputum specimens is a definite and valuable evidence of activity. If bacilli are present in such small numbers that culture or guinea pig inoculation of sputum or gastric contents is necessary to demonstrate them, the significance of the finding in terms of activity is not clear. For example, tubercle bacilli are said to have been demonstrated by such methods in gastric contents of persons whose chest x-ray showed no lesion except calcified hilus glands and even in persons without any demonstrable tuberculous focus.⁴ Such findings obviously cannot be considered as proof of an active pulmonary process at least until such apparently paradoxical results are explained. One must also remember that not all acid-fast bacilli produce tuberculosis. Approximately 50 per cent of gastric specimens

that show acid-fast bacilli on smear will not produce tuberculosis in guinea pigs.⁴ Ten per cent of cases of pulmonary malignancy¹ and an undetermined percentage of lung abscess, bronchiectasis, and other chronic pulmonary lesions occasionally show a few acid-fast bacilli on sputum smears. Therefore, a single report of a few acid-fast bacilli which cannot be confirmed is very poor evidence of activity.

An elevated sedimentation rate, leukocytosis, and an increase in the percentage of polymorphonuclear cells and monocytes are all nonspecific evidence of activity analogous to general symptoms, such as fever, loss of appetite, and loss of weight. In the presence of a tuberculous lesion and in the absence of any other explanation, such evidence is important. The sedimentation rate is the most sensitive and therefore the most valuable of these findings. Just as in the case of symptoms, it should be stressed that negative laboratory findings are of no value in ruling out activity of a tuberculous lesion. Active and progressive tuberculosis with normal sedimentation rate and normal white count and differential is a common occurrence. This is especially true of the so-called subprimary tuberculous lesion which may follow soon after infection in the adult and is by no means an innocuous lesion.²

X-ray findings are the most important single factor in the diagnosis of activity of a tuberculous pulmonary lesion. The x-ray film may permit a definite diagnosis of active disease in the absence of any confirmatory evidence from clinical or laboratory findings.³ On the other hand, negative x-ray evidence, unlike negative clinical or laboratory evidence, is of distinct value in arriving at a diagnosis of stable or inactive disease.

In interpreting the x-ray evidence, three types of findings must be considered: first, the presence or absence of effusion; second, the presence or absence of cavity; and third, the nature of the infiltration. The presence of an effusion, diagnosed by physical findings or x-ray and confirmed by aspiration, should be considered an evidence of active tuberculosis unless some other cause can be found. The presence of cavity is an equally dependable sign of activity of a tuberculous lesion. It is true that occasionally tuberculosis heals completely leaving an epithelialized tissue defect or cavity, but such cases are uncommon and in general the presence of cavity means active disease.

To understand the basis of an x-ray diagnosis of activity in tuberculosis one must be familiar with three different pictures of tuberculous infiltration. The histological significance of these x-ray findings is not yet well understood and the three types of lesions grade into each other without any distinct line of separation. There are also a considerable number of other x-ray appearances that can be produced by tuberculosis but these will not be considered, some because they are so unusual as to be relatively unimportant, and some because they are of no aid in arriving at a diagnosis of activity.

The first important type of infiltration is the so-called "soft" or "exudative" lesion made up of small cottony spots or mottling of rather light density and with hazy and indistinct borders. Such an appearance is not indisputable evidence of tuberculosis, but it is pathognomonic of an active lesion and as such is about as dependable as a positive biopsy in the diagnosis of carcinoma. With such an appearance in all or part of a pulmonary lesion, if the diagnosis of tuberculosis can be made at all, the diagnosis of active disease can be made with assurance, even in the absence of any confirmatory clinical or laboratory data.

The second important type of x-ray lesion is made up principally of streaks or linear shadows with somewhat indistinct margins. Any mottling present is more dense than in the first type of lesion and has more sharply defined borders. With this type of infiltration, the roentgenologist may say that the disease does not appear entirely arrested, but he cannot make a definite diagnosis either of activity or of stability. It may be possible with confirmatory clinical and laboratory evidence to make a definite diagnosis of activity. To diagnose an inactive lesion with such an x-ray appearance, all clinical and laboratory data must be consistent with inactivity and, in addition, the lesion must show no significant change either for better or worse on x-ray examination over a period of several years. Even then the diagnosis of stability should be made with reservations and the patient should not be discharged but should be followed indefinitely with x-ray films at six-month intervals.

The third type of infiltration to be considered is that made up of fine, string-like, sharply demarcated streaks and dense, discrete, and often calcified nodules. In this type of lesion the roentgenologist may diagnose inactive or arrested disease with considerable accuracy but not with absolute finality. No type of x-ray picture gives any assurance that all the tubercle bacilli have been killed or even permanently imprisoned in scar or calcium. Even such an apparently healed lesion may break down, sometimes after years of stability, and produce progressive and dangerous disease. A patient with any definitely tuberculous pulmonary lesion should never be told that his disease is cured or that it is only a scar and of no importance. He should be encouraged to have x-ray films made at six-month or at least yearly intervals throughout his life, so that if reactivation does occur, it will be diagnosed early.

Conclusions

1. A diagnosis of active pulmonary tuberculosis can often be made on the basis of a single x-ray examination even in the absence of any confirmatory clinical or laboratory data.

2. Frequently x-ray examination of a tuberculous pulmonary lesion does not permit any definite diagnosis either of activity or stability, but in many such cases a definite diagnosis of activity can be made with the aid of clinical and laboratory evidence.

3. The absence of clinical and laboratory evidence of activity is of no positive value in establishing a diagnosis of a stable tuberculous lesion.

4. An absolutely dependable diagnosis of healed tuberculosis cannot be established on any basis whatever and therefore all patients with tuberculous pulmonary lesions should be followed indefinitely with repeated x-ray examinations.

CLINICAL-PATHOLOGICAL CONFERENCE

◆ MINNEAPOLIS GENERAL HOSPITAL ◆

Frank C. Andrus, Pathologist

CHRONIC NEPHRITIS AND POLYCYSTIC KIDNEY DISEASE

Presentation of a Case

The case was that of a sixty-year-old colored male who was admitted to the hospital on December 1, 1941, and who expired on December 6, 1941. His first admission to the hospital was in May, 1939, when he complained of dizziness for one week's duration which came on when he stood up or walked. He experienced no dizziness while lying in bed or sitting up. Past history revealed no headaches, diplopia, tinnitus, spots before his eyes, earaches, or buzzing in his ears. He gave a history of having had yellow fever many years ago. The cardio-respiratory and genito-urinary histories were negative save for vague pains in the region of his kidneys on occasion. Physical examination revealed a well developed and well nourished colored male. The pupils were round and equal and reacted to light and accommodation. The blood pressure was 165/100. The pharynx was slightly injected. The cardiac dullness seemed to be displaced to the left. Examination of the chest revealed no râles. The spleen, kidneys, and liver were not palpable. The abdomen was negative. The prostate was slightly enlarged. Remainder of the examination was negative. The laboratory findings on this admission were as follows: The specific gravity of the urine was 1.024; it was acid in reaction and contained one plus albumin, no sugar, 1 to 2 red cells, and occasional pus cells per high power field. The hemoglobin was 86 per cent, the erythrocyte count 4,500,000 and the leukocyte count 6,000. A diagnosis of post-infectious vertigo or mild labyrinthitis was made. The patient was discharged as improved.

He was next seen at this hospital when he was admitted for the last time on December 1, 1941. He had had a sore throat and rhinitis for four weeks, generalized weakness for three weeks, and dyspnea and puffiness of the hands and edema of the legs for three weeks. He also had had anorexia for three days. The patient also had been slightly nauseated for a few weeks but this had disappeared during the last week of his illness. He vomited four to five times but the vomitus was not large in amount. No change had been noted in the genito-urinary system. He had had nocturia two to three times for the past twenty years. There had been no hematuria or history of previous edema or dyspnea. He did not have any visual disturbances, headaches, or chest pains other than a sensation of substernal constriction on exertion.

Physical examination on admission revealed the patient's blood pressure to be 190/110 and the pulse 90

per minute. His breathing was very deep and almost Kussmaul in character. He was not cyanotic or orthopneic. An urinous odor was noted to his breath. There was puffiness of the eyelids. The eye movements were normal and the pupils were normal in their reaction to light and accommodation. The mucous membranes were moderately pale and there was evidence of recent bleeding from the gums. A postnatal discharge was present. The contour of the chest was symmetrical. The breath sounds were normal and no râles could be heard. Examination of the heart revealed slight enlargement of the left ventricular type. The rhythm of the heart was regular and a soft blowing systolic murmur was heard over the apex. The abdomen was flat and the liver edge was not felt. No fluid wave or shifting dullness was noted. No masses were felt. Rectal examination revealed a slightly enlarged prostate. There was a one plus pitting edema of the ankles and lower legs. The venous pressure was 11 cm. of citrate solution. The patient developed an oliguria during hospitalization.

Laboratory findings were as follows: Serologic tests for syphilis were positive. The hemoglobin was 52 per cent with an erythrocyte count of 2,810,000 and a leukocyte count of 10,600. The urine had a specific gravity of 1.015; it contained three to four plus albumin on several occasions, no sugar, no casts, 5 to 6 red blood cells, and 2 to 3 pus cells per high power field. The blood urea nitrogen was 127 mg. per cent and the creatinine 11.5 mg. per cent. The uric acid was 6.5 mg. per cent. The carbon dioxide combining power was 17 volumes per cent. The plasma proteins revealed the albumin to be 5.52 grams per cent, the globulin 2.61 grams per cent, and the fibrinogen .28 grams per cent. A six foot heart plate revealed cardiac enlargement of the left ventricular type. A minimal calcified tuberculosis was noted in the left infraclavicular region.

The patient became markedly hyperpneic. A pericardial friction rub was heard. He became markedly weakened and dyspneic and finally expired on December 6, 1941.

Clinical Diagnosis: Chronic nephritis.

Autopsy Findings (Dr. Fingerma): The body was that of a well developed and well nourished colored male. There was a two plus pitting edema over the pretibial area. Cyanosis was noted over the lips and fingertips. There was no jaundice. The pupils were round and equal and measured 4 mm. in diameter.

Upon opening the abdomen, the peritoneal surfaces were found to be smooth and shiny. The peritoneal cavity contained 1000 cc. of clear fluid. The liver extended 10 cm. below the xiphoid process in the midline and 8 cm. below the right costal margin in the midclavicular line. The pleural cavities were covered with many fibrous adhesions especially around the left apex. The right pleural cavity contained 500 cc. and the left 800 cc. of straw-colored fluid. Upon opening the pericardial sac, a shaggy, fibrinous exudate was seen which had the so-called "bread and butter" appearance over the heart.

The heart weighed 510 grams. The wall of the left ventricle was thickened and measured 22 mm. in thickness. The valves were normal. The root of the aorta was grossly normal. The coronary arteries were patent throughout and contained a minimal degree of sclerosis in a patchy distribution.

The right lung weighed 700 grams and the left lung weighed 670 grams. The large bronchi were filled with frothy mucous. The lungs were edematous. The lungs contained scattered areas of consolidation.

The spleen weighed 170 grams and appeared entirely normal. The liver weighed 1800 grams. The capsule was rather tense. On cut section, the organ appeared congested. The gastro-intestinal tract was normal grossly. The pancreas and adrenal glands appeared normal.

The right kidney weighed 120 grams and the left kidney weighed 115 grams. The kidneys were shrunken and contained coarse deep pits on their surfaces. The capsules were strongly adherent and numerous cysts were seen on the surface and in the parenchyma of the kidneys varying from 3 mm. to 1 and 2 cm. in diameter. The cysts were present in both the cortex and the medulla of the kidneys. About one-third of the lower pole of the right kidney appeared to be the only area of normal kidney structure. The remainder of the kidneys were atrophic and cystic. The genital organs were normal. The bladder was normal.

The remainder of the examination was negative.

Anatomic Diagnoses: (1) Congenital polycystic kidneys; (2) chronic glomerulonephritis; (3) pericarditis; (4) myocardial hypertrophy; (5) uremia.

Discussion

DR. E. T. BELL: This renal disease and hypertension dates back to 1939. He gives a history of nocturia for twenty years. In 1941 he had uremia. He does have some edema which I presume to be cardiac in origin.

DR. G. E. FAHR: I don't think it could be cardiac with a reading of 11 cm. of venous pressure unless he had a higher venous pressure when he was at home and it was not taken right on admission.

DR. BELL: He also has an anemia which presumably goes with his uremia. That would mean that this is a chronic uremia. He has a story of two years of hypertension and uremia. He has a good deal of protein in the urine though he has not lost much protein from his blood. I think that the rather natural diagnosis here, in view of his slow rising blood pressure, would be chronic glomerulonephritis. The anemia means just simple chronic uremia. You can get that in any chronic uremia. I happen to know the answer here. This is a pretty tight case.

DR. FAHR: We have not ruled out polycystic kidneys. This is ruled out by palpation and pyelography. We had one case here where there was no enlargement of the kidneys. The diagnosis could not be made in the usual way. You have to think of very rare things here. The urine shows albumin and occasional white cells. His blood pressure goes up to 190/110 from 165/100; that's a little low, I would say, for the usual case of primary arteriosclerotic kidney disease. What did his eyegrounds show?

DR. L. J. PETIT: There were flame-shaped hemorrhages, but very little arteriolar changes. There was no papilledema.

DR. FAHR: That does not give you much. Flame-shaped hemorrhages do not mean anything.

DR. E. T. BELL: It would only mean hypertension anyway, no matter what. That would not tell us whether he had malignant hypertension, glomerulonephritis, or polycystic kidneys.

DR. FAHR: Was anything palpated in the abdomen?

DR. PETIT: There were no pertinent abdominal findings.

DR. FAHR: If he had a malignant hypertension, he would have had definite eyeground findings.

DR. BELL: With the blood pressure 190/110, he could get hypertensive retinitis; that may be the basis of his renal disease. At least, the question is whether we are dealing with hypertensive type of kidney, chronic glomerulonephritis, polycystic kidneys, or something else.

DR. FAHR: Is there nothing to make you think of a lymphatic infiltration of the kidneys in the blood studies?

DR. BELL: The monocytes are increased a little, but that is all right with a chronic uremia.

DR. FAHR: They get a secondary anemia frequently long before there are any signs in the blood, that is, before there is any azotemia.

DR. BELL: He had an acidosis too, you will notice. He probably had an increase in phosphorous and decrease in blood calcium.

DR. PETIT: The blood phosphorous was 11.9 and the calcium 7.6 mg. per cent.

DR. BELL: The edema was probably due to the fact that he could not put out any fluids. Did you take a culture of the pericardial exudate? We should do that, I think. The few we have taken cultures of have streptococci in them, probably a terminal invasion. That is an uremic pericarditis. He had only one-fourth of his kidney left. He lost about three-fourths of his kidneys from cysts.

DR. FAHR: You have here two kidneys in which approximately three-fourths of the substance is destroyed by cysts. Certainly there isn't one-fourth left in this portion. A man can live on one-fifth of his total portion.

DR. BELL: The interesting thing in this case is that this patient had two types of kidney disease. The polycystic kidney is a hereditary disease. If the history in this man's family be known, there is little doubt but that we would find other examples of it. It is dominant in inheritance. Most of the members of the family will have it. But they may have it in all kinds of degrees. Just like harelip, which varies in degree from a mere slit to a cleft palate, polycystic kidneys may be in different degrees. You can have enough kidney to get along on. In unusual instances, the

kidneys are not enlarged. These are the tougher ones to diagnose. The uremia here is actually due to an associated chronic glomerulonephritis. We can think of this man as having some degree of renal insufficiency through most of his life, I suppose. That suggestion of twenty years of nocturia means he had a compensatory polyuria. The patient had moderate renal insufficiency and secreted urine about the same right through twenty-four hours, therefore, he would have to get up and empty his bladder at night. The normal man at sleep does not excrete much urine; therefore, he does not have to get up. A man with renal insufficiency has to secrete all the time, otherwise he gets uremia. If this man had that twenty years, we can be sure that he had some degree of renal insufficiency. How long he has had glomerulonephritis is not known. They last ten years on an average in all our cases, but may run as long as twenty-five years. So he probably had it a long time. That is a disease that is most

often contracted in childhood but may be contracted any time in life, however.

DR. F. C. ANDRUS: Don't you think that this patient might have lived for some years if it were not for the glomerulonephritis?

DR. BELL: I think that he would have gotten along with one-fourth of his kidney. A rabbit will live with one-fourth of his kidney but his blood urea nitrogen is pretty high. If you take care of him carefully, he will live.

In testing kidney function you only find out how much functioning parenchyma the man has left. You are not testing tubules or glomeruli separately. In any test you use, you are always measuring how much kidney the patient has left. You are not testing the condition of the parenchyma as much as you are testing what he has left to work with.

PNEUMOTHORAX IN PATIENTS OVER FORTY

A survey was made of 431 white World War veterans in whom pneumothorax was instituted or attempted after they had passed their fortieth birthday, during a five-year period beginning January 1, 1935. Every one of the patients had a positive sputum and a roentgenographically demonstrable cavity at the inauguration of his collapse program. Eighty-one per cent had far advanced disease; 19% had moderately advanced lesions. The disease process was unilateral in 49.3% and bilateral in 50.7%. Fourteen per cent had at least one cavity whose diameter exceeded 4 cm. The average age was slightly under 44 years—7% were over 50. The duration of the patients' tuberculosis prior to the attempted induction of pneumothorax ranged from one month to 18 years.

Patients with apparently permanent closure of the cavities and conversion of the sputa were classed as "Successful" and these numbered 92, or 20.2%. The "Unsuccessful" numbered 48.7% and the "Impossible" 31.1%. The various complications of artificial pneumothorax occurred with no greater frequency than among younger patients. Death was due directly to the complications of pneumothorax in 5 patients. Sixteen of the patients who died had pure tuberculous empyemata, though it is difficult to estimate the degree in which the presence of intrapleural pus contributed to these deaths, for in all cases the pulmonary lesion was actively progressive. Including these 16 cases, the fatalities consequent to complications would number only 21 or 4.9% of the patients treated, about what may be expected in general.

The shorter the time the patient has been ill and the less extensive his lesion, the greater the chances for the

success of the therapy and the smaller the probability of occurrence of empyema. Closure of the cavity is effected earlier in patients whose disease history has been brief, though pleural effusions (a complication of little significance in most cases) are more likely to supervene in persons who have had tuberculosis only a short time.

The time interval of cavity closure and sputum conversion varies directly with the patient's age; most of the pneumothoraces became successful in the latter half of their first year. It seems advisable, therefore, to maintain pneumothoraces of doubtful efficacy for a longer time in persons over forty than would be wise in younger patients.

Bilateral pneumothorax, properly administered in carefully selected cases, is well tolerated and ordinarily occasions no marked respiratory embarrassment. The surgical division of pleural adhesions is necessary to the completion of the collapse in a large number of persons in the fifth decade, just as it is in younger patients.

Weighing the results and the complications, the authors conclude that artificial pneumothorax is of distinct value in the treatment of patients over forty. It is not as effective as in younger persons, but neither is any other therapeutic measure. Thus far it appears that artificial pneumothorax is enduring in its effects in persons over forty, but final conclusions cannot be drawn until most or all patients in the successful group have been observed for a sufficient length of time after reëxpansion to permit accurate estimation of the lasting effectiveness of their pneumothorax.—*Artificial Pneumothorax in Patients Over Forty* by SIDNEY DIAMOND and HUBERT T. IVEY, *Amer. Rev. of Tuberc.*, Apr., 1941.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF THE MINNESOTA STATE MEDICAL SOCIETY

By ARTHUR S. HAMILTON, M.D.

Minneapolis, Minnesota

(Continued from January issue.)

On February 1, 1870, the Society met in the Historical Society Rooms in Saint Paul, on the first anniversary of its founding.

The president, Dr. Willey, addressed the members in the following words of welcome, which seem worthy of preservation:

Gentlemen of the Minnesota State Medical Society:

Assembled today upon the first anniversary of the formation of this Society, it becomes alike my duty and my privilege, to bid you, each one and all, a hearty welcome.

The incentives which have brought together so large a body of professional men at this inclement season of the year, many from remote sections of the state, and all at no little trouble and expense, are not the incentives of self-interest or self-congratulation, but they spring, we humbly trust, from the noble desire of sustaining and building up the profession we honor—the science and art of rational medicine—by meeting, consulting, and interchanging views upon subjects which everywhere and always must affect the well-being of communities. Let us lay broad and deep the foundation of a Society of which we may in time feel proud, and which shall endure, let us fervently hope, long after the responsibilities which now weigh on us have descended to other hands.

In commencing our labors, then, today, let us prominently bear in mind that no sectional interests, or motives merely personal, should influence our deliberations, but that a purely catholic spirit should pervade and govern us, so that in all our doings we may work harmoniously together for the advancement, usefulness and honor of our profession. Again, gentlemen, I bid you a cordial and hearty welcome.

Drs. Boardman, Kimball and C. E. Smith, a committee on credentials, reported thirty physicians as duly qualified for membership, and, on motion, they were elected.

Drs. J. H. Stewart, Richardson, Wharton, C. P. Adams and O. J. Evans appointed a committee to nominate officers for the ensuing year, submitted the list as appears in the table of officers,[†] and their report was unanimously adopted.

A committee at this meeting, through Dr. Richardson, also reported on the origin, cause and treatment of typhoid fever. It would be interesting at this date to know what was then current belief in so important a matter but, unfortunately, the record is not available.

Felicitations were exchanged with the New York State Medical Society.

The committee on Dr. Willey's prizes for the essays on "Epidemics and Endemics of Minnesota" and on "Cerebrospinal Meningitis" awarded both to Dr. W. W. Sweney of Red Wing, who modestly declined to receive the money awarded him, and endorsed the check to the Society as a "prize fund" for the ensuing year.

The president announced the following standing committees:

Executive Committee.—C. P. Adams, Hastings, Chairman; Franklin Staples, Winona; C. K. Bartlett, St. Peter; J. B. Phillips, St. Paul; C. E. Smith, St. Paul.

Finance Committee.—A. G. Brisbane, St. Paul, Chairman; W. H. H. Richardson, Winona; S. B. Sheardown, Winona; E. J. Davis, Mankato; J. E. Finch, Hastings.

[†]Hereafter the reader is referred to the table at the end of this article (to be published in a later issue) for the results of the annual election of officers.

HISTORY OF MEDICINE IN MINNESOTA

Publication Committee.—C. H. Boardman, St. Paul, Chairman; S. D. Flagg, St. Paul; D. W. Hand, St. Paul; E. H. Smith, St. Paul; S. B. Sheardown, Winona.

Committee on Ethics.—C. G. Goodrich, Minneapolis, Chairman; A. Wharton, St. Paul; C. Hill, Pine Island; W. W. Mayo, Rochester; Otis Ayer, Le Sueur.

Committee on Medical Societies.—F. H. Milligan, Wabasha, Chairman; A. B. Hawley, Red Wing; A. E. Ames, Minneapolis; J. B. Griswold, Taylors Falls; A. B. Stuart, Winona.

Board of Censors.—D. W. Hand, St. Paul, Chairman; A. Wharton, St. Paul; C. K. Bartlett, St. Peter; C. G. Goodrich, Minneapolis; L. Redmon, Preston.

Essayist for the Semiannual Meeting.—Dr. A. W. Daniels, St. Peter; Dr. S. D. Flagg, St. Paul (alternate).

Delegates to the American Medical Association.—H. H. Kimball, Minneapolis; C. A. McCollum, Minneapolis; J. H. Stewart, St. Paul; C. E. Smith, St. Paul; A. C. Wedge, Albert Lea; B. B. Palmer, Sauk Center; Wm. Thorne, Hastings; J. B. LeBlond, Brownsville; W. W. Mayo, Rochester.

Delegates to the National Pharmaceutical Convention.—A. B. Hawley, Red Wing; David Day, St. Paul; J. Perham, Anoka.

The president also announced the following special committees:

On Epidemics, Climatology and Hygiene.—W. W. Sweney, E. C. Cross, B. Mattocks, J. B. LeBlond, James S. McMasters.

On Practical Medicine.—C. H. Boardman, A. G. Brisbane, H. F. Noyes, Hector Galloway, J. B. McGaughey.

On Surgery.—F. Staples, J. H. Murphy, C. N. Hewitt, F. H. Milligan, E. J. Davis.

On Obstetrics and Gynecology.—A. W. Daniels, A. Wharton, A. J. Stone, Otis Ayer, W. L. Lincoln.

On Dermatology.—W. Banks, F. M. Rose, A. E. Senkler.

Dr. Hewitt, who was appointed essayist at the preceding annual meeting, read an essay on "The Relations which the Profession Sustains to the Public and the Duties Which These Relations Impose"; and, in the absence of Dr. A. E. Ames, who was in California during a portion of this year, Dr. Hutchinson read the address which Dr. Ames had prepared for the meeting. Unfortunately, neither address is now available.

Dr. Rhodes offered the following resolution, which was adopted:

RESOLVED, That in the opinion of this Society, laws so formed as to protect the people from the impositions of unqualified pretenders to the practice of Medicine and Surgery, would result in good, and further, that we believe that they could be so worded as to afford such protection; but we wholly disclaim any desire upon our part to have such laws on account of any benefit to us as medical practitioners.

Dr. A. B. Stuart offered the following preamble and resolution:

WHEREAS, Bidding or proposing for public or private business, especially where it renders the party liable to come in conflict with other members of the profession, has a tendency to lower the dignity of the profession, both in the estimation of its members, and in that of the public; therefore,

RESOLVED, That such bidding or proposing is, and shall be considered, unprofessional.

This resolution shall not be so construed as to apply to the acceptance of a position upon a stipulated salary.

The minutes do not clearly show what action was taken on this resolution other than that it was accepted and placed on file. The profession being then very much as it is now, it is likely that no further pressure was brought to bear on this chronically tender point.

As the meeting of February 1, 1870, in Saint Paul was the first at which a formal presidential address was given, it seems proper to quote Dr. Willey's address in full.

PRESIDENT'S ADDRESS

Gentlemen—

It is a requirement of our bylaws, and is both customary and proper, that such remarks shall be made by your executive officer, at the expiration of his term of office, as he may deem most conducive to the welfare and prosperity of the Society.

I do not propose a didactic essay, but simply desire to speak a few plain words, in the hope that our Association and its objects shall be steadily and earnestly sustained and persevered in, and that the good results which are already so apparent may be greatly augmented as the coming years pass before us.

Thus far, our meetings have been characterized by the utmost harmony—our number is rapidly increasing by the enrollment of good men from all sections of the state—and we may safely assert that the organization is already one of which, not only ourselves, but the citizens of Minnesota, may justly feel proud.

Physicians occupy the position of conservators of the public health—and, as health is the chiefest of all earthly blessings, those who by their skill contribute most to its preservation, and its rescue when in peril, are the greatest public benefactors.

Thus, as no communities are indifferent to the character and skill and ability of their medical advisers, we may rest assured that our efforts for mutual improvement in scientific attainments are silently appreciated and commended by all.

During the past year, old County Societies have renewed their vigor, and several new ones have been formed—these, as auxiliaries, will be henceforth pillars upon which the Society will securely rest.

While I fain would mention some which have worked very important results, yet it might appear invidious to others which have not done so well.

It is my duty, however, to recognize all transactions of Societies *officially* transmitted to me, and I therefore have to announce the following action of the Hennepin County Medical Society, duly attested by its able Secretary:

WHEREAS, Action of this body has been deemed necessary in order to prevent professional quackery in the matter of publishing surgical operations, etc., in the public journals:

RESOLVED, That any member of this Society who shall permit his name to appear in connection with a report of a surgical operation, or case of disease, in the public prints, or who shall furnish any secular journal with any such report for publication, shall be deemed guilty of gross violation of the Medical Code of Ethics, and of professional honor.

RESOLVED, That it shall be the duty of the Committee on Ethics to investigate each case, as it appears in print, and report the result to the Society at its next regular meeting; and the offender, if found guilty, shall be reprimanded by the President for the first offense, and summarily expelled for the second.

A true copy.

(Signed)

W. F. HUTCHINSON, M.D.

Secretary.

These are in strict accordance with the Code of Ethics of the American Medical Association, and I trust each County Society will adopt, and strictly enforce, similar judicious resolutions.

As the population of our state becomes less sparse, and our numbers increase, I trust that even the very remote counties will not be without well-organized, working societies.

As Minnesota is looked upon in this country and throughout Europe as a sort of sanitarium for many diseases, particularly those of the pulmonary organs, each Society should have its committee on climatology and epidemics, which should report annually to this Society, that statistics may be properly compiled and preserved.

I would further recommend that each member briefly record the name and type of every case of disease observed, so that at the close of each year, statistical information may be obtained of interest to the profession, and of vast importance toward a knowledge of the sanitary status of our state.

To ask the busy practitioner to record cases, as in hospital practice, is to ask what would rarely be performed; but the suggestion above implies no real labor, and its fulfillment will bring to each of you ample reward.

In this connection, I would respectfully suggest the appointment of a committee at this meeting to confer with our medical brethren in the Legislature, with a view to the preparation and passage of a bill providing for the registration of births, marriages and deaths. Connected with and under the supervision of the present able bureau of general statistics—now comprising agriculture, manufactures and population—the collection of *vital statistics*

would, to use in part the language of Dr. F. B. Hough, the able superintendent of the New York State Census, in 1855 and 1865, "form the basis of computations for life insurance, and present the elements of what is necessary to be known concerning the probabilities of life at different ages, the origin, range, and mutability of epidemics, and the influence of age, sex, locality and season upon disease."

The form of bill presented by Dr. Hough to the New York State Medical Society is an admirable one, and, with some modification for change of locality, would answer well the purpose.

All enlightened governments are actively alive to the immense importance of vital statistics, and Minnesota has never yet been backward in any work tending toward her social and political advancement.

At the last session of the Legislature, an act was passed with a view to the protection of the people from the evils of empiricism and quackery, and although I am informed by some of the members of that body that good has been accomplished in their respective neighborhoods, by summarily arresting the career of imposters, yet the law was a defective one in many respects, with no provision for its enforcement, and it has not met the expectations of its framers, or of the people.

That the principle involved is a correct one, admits of no doubt, but the application of legislative enactments in overthrowing the frightful evil has ever been a difficult one.

It has been suggested that this law, which is practically a dead letter, should be properly amended—also, that an act should be passed providing for a "State Board of Censors," to be appointed by the Governor, by and with the advice of the Senate, and, as in the admission of members of the other learned professions, make the *professional attainments and moral character* of the applicant the only tests for admission to practice in the state, without reference to any private opinions he may entertain.

All this is submitted to your better judgment for consideration, with the understanding that they are suggestions, not deliberate recommendations.

This is not "class legislation"—it is not for the benefit of the few against the many, but the very opposite—it is not for the benefit of the medical profession, as is so often falsely alleged—but it *aims at direct protection of the people against hurtful classes of men.*

Laws are enforced against those who, as thieves and assassins, despoil your property, or injure your persons—those who by false pretenses, and for their own base and selfish purposes, tamper with the health and lives of the afflicted. Such persons belong to a similar class of criminal offenders against public policy, and should be as promptly dealt with.

Steel said, in the *Spectator*, a century and a half ago: "There is hardly a man in the world, one would think, so ignorant as not to know that the quack-doctors who publish their great abilities are, to a man, impostors and murderers."

The public should know that all advertisements, circulars and certificates, calling attention to special branches of medical practice as inducements to patronage, stamp the authors at once as charlatans, and disqualify them from fellowship with honorable members of the profession.

A distinguished writer says: "The world is peopled by two classes of beings, who seem to be as cognate and necessary to each other as male and female.

"Charlatans and dupes exist by a mutual dependence.

"All bills which the former draw, the latter come forward at once and honor."

These quacks are not infrequently quite grave and reverend individuals, and exemplify the saying of Lord Bolingbroke, that "gravity is the essence of imposture," or of the humorist who said "The gravest beast was an ass—the gravest bird an owl—the gravest fish an oyster—and the gravest man a fool."

But this is of far more moment to the general community than to ourselves, as it is capable of demonstration that diseases are continually being created, as well as aggravated, by quacks and their remedies.

No man of self-respect, in any profession, will care how many practitioners center in his neighborhood, but will cheerfully welcome all of good standing—as it may be supposed the supply rarely exceeds the demand—yet no one of humane feelings can but deeply regret, when the community in which his lot is cast and in which he has a common interest at least, becomes the prey of cunning charlatans, who by smoothly worded promises, and specious practices, makes those who should be the subjects of the tenderest regard, and most skillful care—the sick and the suffering—the objects of spoliation and wanton experiment.

Enough of this. Addison says that, "Like the imperceptible insects which are discovered by the microscope, they cannot be made the subject of observation without being magnified."

The people being the source of political power, legislation is of course subservient to

popular sentiment and intelligence, and by educating the latter upon the foregoing points, the greater good, perhaps, may be obtained.

Medicine is essentially a practical science, and the merest tyro knows how brief has been the existence of systems based upon speculations and theories, instead of observation, analysis and induction.

While hobbies and dogmas and theories are to be avoided, it is well that each should strive to become proficient in one or more branches of our art, toward the study of which his inclination and mental habits lead him.

One must not only be well grounded in the elementary principles of medicine, but be above mediocrity in the practice of its several branches, before he can study special diseases with signal benefit—then, carrying out such study in an enlarged spirit, inclines to a better appreciation of disease in general.

Those of our medical brethren in the East, who are thus engaged, and whose names are as familiar as household words, are scarcely less erudite in other branches of medicine.

In my intercourse with members during the past year, it has been in the highest degree gratifying to note the liberality with which they patronize journals, and other current and standard medical literature.

One cannot overestimate the value of medical journals to the busy practitioner, particularly to him who is debarred from frequent fellowship with his brethren.*

There is no royal road to medicine, as there is none to heaven, or geometry, and it is only by careful observation, diligent reading and reflection, and the cautious application of deductions, that the physician becomes in time the scientific medical man.

A word upon a subject which justly claims no little attention. The almost criminal laxity with which examinations for life insurance are frequently made, is of incalculable wrong to the insurer and the insured. The examiner is not only the chosen, confidential adviser, but he holds the most important interests of his company, in his vicinity, under his control.

He should be alive to this great responsibility, and strive to become, not only a thorough diagnostician, but an expert in this particular sphere—he must not only be able readily to detect functional diseases and internal lesions, but he is appointed to a still higher task—he is to judge *prospectively* of the life of the applicant.

Goethe says: "Nature defies incompetency, but reveals its secrets to the competent, the truthful and the pure."

A few words more. Let us all remember that while we seek fame and fortune as proper objects of desire, yet that the practice of our profession should rest upon that philosophy which arises from "the noblest faculties of reason, and of the cardinal virtues of the soul."

Respecting our profession, we cannot but respect all fellow workers; and in our intercourse with each other, we should be full of that charity which is not strained, "but droppeth as the gentle rain from Heaven."

Especially should we assist and support our juniors.

Ordinarily, the lot of the young physician is tedious and toilsome, no matter how able and deserving he may be; to place obstacles in his upward progress to an honorable position and its compensations is cruel and unmanly; to cheer him on his professional way with kind words and still kinder actions is the part of the upright senior and fulfils the precept of the golden rule "Thy neighbor as thyself."

Our profession is not only governed by the code of laws of the American Medical Association, but it has a natural code of laws springing from a reciprocal system of feelings and sympathy pervading its members.

May this sympathy and fraternal spirit ever animate us—and may our profession ever be our study, our pride and our enthusiasm.

A special committee on the President's Address, submitted the following report, which was adopted:

The committee would respectfully report that they have given the suggestions of the address careful consideration, and advise the adoption of the following resolutions:

RESOLVED, That the Society reiterates the request made at the last annual meeting, to all members of the profession throughout the state, who have not already done so, to organize county societies.

RESOLVED, That said Societies be advised to make it incumbent upon their members to report annually the statistics of the diseases occurring in their practices, and that their Secretary report a summary of the same to this Society.

*See David Fairchild's article (to be published in a later issue).

We advise the adoption of a bill similar to that proposed by Dr. Hough to the New York State Medical Society, as in every way suited to the purpose of providing for the collection of vital statistics, and that with this recommendation, the matter be referred to our professional brethren in the Legislature.

Your committee, after serious deliberation, express the belief that laws regulating the practice of medicine, do not, and can not, reach the cause of the success of quackery among the people, but that that cause is to be found in the deficient knowledge on the part of the people in regard to the real ground upon which the practice of medicine rests, and that so long as that deficiency exists, quackery will flourish. If legislative action is to be had, it should be directed to the removal of that cause.

CHARLES N. HEWITT,
A. E. SENKLER,
C. HILL,
C. H. BOARDMAN.

Dr. Willey's recommendation in favor of an investigation of the climate of Minnesota and its relation to epidemics, a provision for vital statistics, a qualification for medical practice much as now employed, and his insistence on thorough fundamental preparation as preliminary to specialism in medicine show a desire for original investigation and an understanding of the essentials of medical practice quite equal to much more modern views on these subjects.

Dr. Wharton, for the committee appointed at the last annual meeting to prepare a Constitution and By-Laws, submitted a draft which after several amendments was adopted as follows:

CONSTITUTION of the MINNESOTA STATE MEDICAL SOCIETY

ARTICLE I

Section 1.—This Association shall be called the "MINNESOTA STATE MEDICAL SOCIETY," and shall be composed of members and honorary members.

Section 2.—There shall be an annual and a semi-annual meeting of the Society.

The annual meetings shall be held in the city of St. Paul, on the first Tuesday in February. The semi-annual meetings shall be held on the second Tuesday in June, the place to be determined by the Society at each annual meeting.

The object of the semi-annual meetings shall be more especially the promotion of professional culture and education.

Special meetings may be called by the President, upon the petition of ten members, twenty days' public notice being given previous to such meeting, in one or more of the daily papers published at St. Paul.

At all meetings fifteen members shall constitute a quorum.

ARTICLE II

Section 1. The Society shall constantly have in view:

First: The association of the profession for mutual recognition and fellowship.

Second: The maintenance of union, harmony and good government among its members, thereby promoting the character, interests, honor and usefulness of the profession.

Third: The cultivation and advancement of medical science and literature, and the elevation of the standard of professional education.

ARTICLE III

Section 1.—The members of this Society shall be regular practitioners of medicine and surgery in the State of Minnesota, who shall be elected by a vote of the majority, at any regular meeting, their eligibility having been previously reported upon by the Committee on Membership.

Section 2.—The officers of the county or district societies are required to report each year to the recording secretary of the state medical society, if auxiliary thereto, the names of all their members, to serve as a basis for the medical statistics of the state; and no physician

HISTORY OF MEDICINE IN MINNESOTA

not in good standing in his own county or district society shall be admitted as a member of the state medical society.

ARTICLE IV

Section 1.—Honorary members shall only be admitted by a vote of two-thirds of the members present at a regular meeting, having first been recommended by the Committee on Membership.

ARTICLE V

Section 1.—This Society shall have the power to censure or expel any member convicted of violating its provisions, or who may be guilty of any act which may be considered derogatory to the honor of the medical profession; but a vote of four-fifths of the members present shall be requisite for the expulsion of a member, which vote shall be had in consequence of a report from the Committee on Ethics, and at the next regular meeting subsequent to such report.

ARTICLE VI

Section 1.—The officers of this Society shall be a president, three vice presidents, a recording secretary, a corresponding secretary, and a treasurer, all of whom shall be elected annually, upon the report of a nominating committee, at the regular annual meeting. They shall severally perform the duties assigned them in the By-Laws, as shall also the standing committees.

ARTICLE VII

Section 1.—The following standing committees shall be annually appointed by the president, and shall each consist of five members: 1st, an Executive Committee; 2nd, a Committee on Finance; 3rd, a Committee on Publication; 4th, a Committee on Ethics; 5th, a Committee on Medical Societies.

Section 2.—The President shall appoint at each annual meeting, five censors, who shall be known as the "Board of Censors." They shall perform such duties as are assigned them in the By-Laws, and in the manner there prescribed.

ARTICLE VIII

Section 1.—County or District Societies may become auxiliary to this Society, by transmitting a copy of their Constitution and By-Laws for examination and record, and electing delegates to the annual meeting of this Society.

Section 2.—No county or district medical society, auxiliary to this Society, shall, by censor or otherwise, grant diplomas, or confer any right to practice medicine or surgery.

ARTICLE IX

Section 1.—No part of this Constitution shall be repealed, annulled, altered or amended, except at a regular meeting subsequent to one at which a proposition to that effect may have been made in writing, and then only upon a vote of two-thirds of the members present.

BY-LAWS

of the

MINNESOTA STATE MEDICAL SOCIETY

ARTICLE I

Section 1.—The president shall preside at all meetings, enforce a due observance of the Constitution and By-Laws; see that all officers and members of committees perform their respective duties; appoint all committees not otherwise provided for; give the casting vote only; sign diplomas and all other official documents requiring his signature and perform such other duties as pertain to his office by usage and custom.

Section 2.—The vice presidents shall assist the president in the performance of his duties, and in his absence shall preside in order of rank.

Section 3.—The Recording Secretary shall keep the minutes of the proceedings of all meetings, notify officers of their election, sign diplomas, and certify to all official acts requiring the same; receive the signature and initiation fees of the newly elected members, and do such other business as shall be required or as the Society shall from time to time

direct. He shall notify each member when his name occurs on any of the committees, which have work to perform for the next meetings, within two weeks after adjournment.

The corresponding secretary shall attend to such duties as naturally pertain to his office.

Section 4.—The treasurer shall receive all moneys due the society and pay all bills audited and approved by the Finance Committee, and countersigned by the president, keeping correct account of the same, and making a full and detailed report at the annual meeting.

ARTICLE II

Section 1.—The Standing Committees shall keep regular minutes of their proceedings, and furnish an authenticated copy to be deposited with the recording secretary.

Section 2.—The Committee on Ethics shall investigate all complaints of breach of etiquette or violation of medical ethics, and it shall decide all questions of ethics submitted to it. If any member shall be charged in writing with any violation of the provisions of the Constitution or By-Laws, or with unprofessional conduct, a copy of such charges shall be furnished him, and himself and his accuser cited to appear, when the committee shall proceed to hear the case, reserving its decision to be reported to the Society, when its action may be affirmed by a vote of four-fifths of the members present.

Section 3.—The Committee on Finance shall superintend all the monetary affairs of the Society, inspect and audit all bills and the accounts of the treasurer, and make such an assessment, by a pro rata tax upon the members, as may be necessary for incidental expenses.

Section 4.—The Committee on Publication, of which the recording secretary and treasurer shall be members, shall prepare, publish and distribute such of the proceedings, transactions, and memoirs of the Society as may be selected for publication; it shall supervise and edit all papers presented to the Society and ordered to be printed and report its doings at each annual meeting.

Section 5.—The Executive Committee shall digest and prepare the business of each meeting, recommend plans for the promotion of the objects of the Society, and in all things protect and superintend its general interests.

Section 6.—The Committee on Medical Societies shall consider and report on the organization of such associations as may desire to become auxiliary to the State Medical Society, and generally take charge of this department, making at each annual meeting as complete a report as practicable.

Section 7.—It shall be the duty of the "Board of Censors" to examine all applicants for the diploma of this Society. Three censors shall constitute a quorum. They shall require satisfactory proof of the applicant that he has studied medicine with some physician and surgeon duly authorized to practice his profession, at least for three years; that he has attended at least one course of lectures in a school of medicine recognized by the American Medical Association; and that he has been in reputable practice for a period of not less than five years; and that he is of good moral character. They shall then proceed to examine him in the several branches of medicine and surgery, and if such examination is satisfactory, they shall give a certificate to that effect to the president or recording secretary of the State Medical Society.†

Section 8.—On the presentation of such certificate from the Board of Censors, the president and recording secretary shall be, and are hereby authorized, to grant to every such candidate qualified to practice medicine and surgery agreeably to law, in the name and under the seal of the Society—a diploma in the following words, viz:

To all to whom these presents shall come or may in any wise concern: The president and members of the Minnesota State Medical Society send greeting:

WHEREAS (*Name and county of the candidate*) hath exhibited unto us satisfactory evidence that he hath studied medicine and surgery, for the time and in the manner directed by law, and hath, also, upon examination by our censors, given sufficient proofs of his proficiency in the healing art, and of his moral character: Therefore, by virtue

†The following items from the *Minneapolis Tribune* throw light on the significance of Sections 7 and 8: (*Minneapolis Tribune*, September 26, 1869): "A meeting of the Board of Censors of the Minnesota Medical Society will be held in Rochester on Thursday, the 30th of September, at the office of Dr. Mayo to examine parties not already legally authorized who may wish to receive authority to practice medicine." The subsequent papers make no reference to this meeting, but the following item is explanatory.

(*Minneapolis Tribune*, October 1, 1869): "The Medical Profession—At the last session of the Legislature, a law was enacted requiring all practitioners of medicine on or before the first of October, to file with the clerk of the District Court of the county wherein they practice, a copy of their diplomas, or a certificate of some county or state medical society, and subjecting all who attempt to practice medicine without first complying with this law, to a heavy fine. During the past few days the doctors in this vicinity have been busy hunting up their diplomas and certificates and filing them with the clerk of the court. About thirty have already complied with the law, while a number have failed to come to time. There will be lively times if some of these doctors are made to pay their fines."

of the power vested in us by law, we do grant unto the same (*name of the candidate*) the privilege of practicing medicine and surgery in this state, together with all rights and immunities which usually appertain to physicians and surgeons.

In witness whereof we have granted this diploma, sealed with our seal, and certified by our president and secretary. (*Place and date.*)

Section 9.—Before receiving such diploma the candidate shall pay to the recording secretary the sum of fifty dollars, and sign the following declaration:

I, A-B, do solemnly declare that I will honestly, virtuously, and chastely conduct myself in the practice of medicine and surgery, with the privileges of exercising which profession I am now to be invested; and that I will with fidelity and honor do everything in my power for the benefit of the sick committed to my charge. Which said declaration, so signed, shall be filed by the secretary in the archives of the Society.

Section 10.—The censors shall report annually to the Society the number and names of the candidates examined by them during the year.

ARTICLE III

Section 1.—Any member vacating his membership shall thereby be divested of any right or title to any portion of the funds or other property of the Society.

Section 2.—Every member, on admission, shall pay the sum of three dollars, as an initiation fee, and sign the Constitution and By-Laws, nor shall he be entitled to the rights of membership until the same is done.

Section 3.—All vacancies shall be filled, ad interim, by the president.

Section 4.—These By-Laws may be suspended by a three-fourths vote, at any regular meeting, and they may be repealed or amended by a similar vote, notice of the same having been given, in writing, at a previous meeting.

Section 5.—Rules of order, and all questions arising upon the same, shall be determined by parliamentary usage.

ARTICLE IV

Section 1.—This Society adopts, as part of its regulations, the Code of Ethics of the American Medical Association.

Just preceding the close of the meeting, the following resolution, on motion of Dr. Davis, was adopted:

RESOLVED, That the thanks of this Society are due, and are hereby tendered to the President, Dr. Willey, for the valuable aid he has rendered in perfecting its organization, and for the impartial and dignified manner in which he has presided over its deliberations; also, to the Committee on Arrangements, and to the physicians of St. Paul, for their generous hospitality and fraternal kindness.

On motion the meeting adjourned.

(*To be continued in March issue.*)

President's Letter

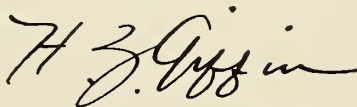

INDUSTRIAL health and industrial medicine automatically at this time take the center of the stage. Industrial medicine includes industrial hygiene and sanitation, industrial surgery, occupational disease and industrial psychology. The war effort demands not only industrial expansion of a stupendous degree but dislocations of personnel which complicate the situation. Fortunately our State Board of Health in its continuous program has been not only on the alert but has been busy accomplishing things. Its various divisions have been farsighted and active. Last fall the Office of Civilian Defense called a conference of representatives of the State Medical Association, the State Dental and Veterinary Societies, the State Nurses Association, and the State Board of Health to evaluate the status of medical health in defense. Later, the Sanitary conference gave over most of its program to medical health in civilian defense. In general, it seemed that the most logical procedure was the expansion of certain activities—nutrition, vaccination and immunization, first aid and safety measures, child health and industrial health—these objectives to be furthered in coöperation and coördination with all existing agencies in the state interested in these various fields. It was obvious that industrial health was of immediate concern. Although Minnesota is not ordinarily thought of as an industrial state, nevertheless in actual number of workers it stands in the upper third among the states.

A three-day Congress on Industrial Health under the sponsorship of the Council on Industrial Health of the American Medical Association has just been held in Chicago. Its reports and papers, to be published in the *Journal of the American Medical Association*, will be especially interesting. It was brought out very clearly that special training is necessary to supply industry with qualified physicians, and that at present there is so serious a lack of qualified physicians that urgent action is necessary. A twenty-hour course in industrial medicine and occupational disease in the senior year was regarded as essential and a six weeks' service in a plant hospital during internship, desirable where possible. Physicians who wish to enter this field as a specialty require graduate courses and longer internship. Schools of industrial hygiene and health are needed as we formerly needed schools of public health and preventive medicine. The medical needs of an industrial age are not being supplied.

In the meantime what can each physician do and what can the State Association do to bridge the gap? The knowledge of the practicing physician in methods of resuscitation and treatment of wounds, burns and fractures is a basis for industrial surgery and every effort should be made to keep informed along these lines. Knowledge can be gained by visiting the emergency hospitals of industrial plants—a knowledge which may be much more interesting and valuable to physicians in general practice than that obtained at famous clinics. A knowledge of industrial hygiene and of occupational disease is quite another matter and probably can be learned best in postgraduate courses or by actual experience in the plant. However, we can expand our histories to include a more careful analysis of occupation and environment in relation to the patients' illnesses, and keep careful records. In Iowa, institutes of industrial medicine have been held in several cities of the state by the State Health Commission and the State Medical Association. Other State Associations have tried other methods of instruction. Medico-legal problems involving the liability of the employer and the relation of the attending physician to the employee in the matter of compensable disabilities are of concern to all practitioners. Is our existing legislation up to date and fair to employer and employee?

Our Committee on Industrial Health under Dr. J. L. McLeod was very well represented at the Congress on Industrial Health; the members of the Committee have these matters under consideration and I am sure you will hear from them. Dr. L. W. Foker, director of the Minnesota Division of Industrial Health, is conducting investigations of the situation in various industries of the state, and is offering technical, medical, and engineering service to assist industry in the control of industrial hazards. He has prepared a report blank of industrial or occupational disease which will be distributed to all physicians. The new section on Industrial Health, in MINNESOTA MEDICINE, will keep us informed.

World War I was responsible for the promotion of public health and preventive medicine and also for the early phases of progress in industrial health. World War II doubtless will prove a great impetus to industrial hygiene and industrial medicine.

INTERNATIONAL FORCE OR ORDER?

SOME individuals and some nations believe that war is a biological necessity in the working out of the survival of the fittest. In the philosophy of the Nazis the nation entitled to dominate is the one best able to invent and construct weapons of destruction and the energy to subjugate its neighbors by force and treachery. Peaceful relations with neighbors and respect for treaty obligations receive no consideration. The law of the jungle is the only law the Nazis know.

Japan has shown herself an able imitator of western civilization. She has thoroughly adopted the philosophy of the Nazi and applied it since

her first invasion of China. No doubt the Japanese have been viewing with alarm the marvelous development, both educational and industrial, going on in China the past fifteen or twenty years. To a nation like Japan that considers force the determining factor in international relations, a China developed along the lines of western civilization with modern weapons of war was a threat to be prevented, if possible. Hence, the destructive war which has been going on over four years.

The Japanese have undoubtedly been pressed for room. As brought out in a recent Bulletin of the Metropolitan Life Insurance Company,* the small island of Japan, no larger than the state of California, has a population of 490 to the square mile. Colonizing efforts on the part of the Japanese government to encourage emigration have not been very successful. The island of Japan is not sufficient in size or fertility to produce food stuffs for so many mouths and she must depend on importation of food and exportation of manufactured goods. Japan's position is much like England's. However, in England the population is more dense than in Japan, there being 700 inhabitants to the square mile. In Belgium, too, the figure is 706 to the square mile. These two countries have not attempted to enslave their neighbors, but have become industrial nations, have imported the additional needed food and have attempted to live in peaceful relations with their neighbors.

The population of Japan has been increasing, according to the Bulletin, at the rate of better than 1 per cent per year, until the war began. Each year some two million Japs have been added to the population of Japan—nearly as many as our two and a quarter million. This, however, does not satisfy the Japanese government which is carrying on active plans like the German and Italian governments to encourage greater increase in population. The excuse for recent encroachment on her neighbors is the teeming population in Japan, but the Japanese government is incongruously doing everything possible to increase that excuse.

One fact that has been overlooked in initiating

*Population Problems in Japan. Statistical Bulletin Metropolitan Life Insurance Company, 22:1, (Dec.) 1941.

the present struggle is that no one nation or group of nations so far allied can enslave the rest of the world permanently. The love of freedom and national patriotism are too strong factors to be long stifled. After this war is over the world will need an international organization with a police force behind it to assure the independence of nations, large and small, and to enable them to work out their destinies without fear of destruction by their neighbors.

POLIOMYELITIS, AN ALIMENTARY INFECTION

A RATHER complete résumé of the addition to our knowledge of poliomyelitis since 1934 appeared in the Progress section of the *American Journal of Medical Sciences* for December, 1941. Although admittedly little has been added in these recent years, and much remains to be learned before the infection can be prevented, certain facts have been fairly well established.

It is generally accepted that poliomyelitis is due to a filterable virus which can pass through the finest filters and membranes known. The virus has sufficiently distinct properties to permit its identification with as much certainty as it is possible to identify any well-known bacteria.

According to Sabin, the disease is contracted through the alimentary canal and multiplication occurs in the walls of the pharynx and small intestines. Elimination occurs in the feces. Whether the multiplication occurs in the nerve cells of the walls of the alimentary tract or in the non-nervous tissues is not known, but it is believed that the virus invades the central nervous system by two pathways, one leading to the medulla by way of the cranial nerves supplying the upper part of the tract or by the vagus, and the other by the way of the sympathetic fibers from the intestines to the spinal cord.

Extension from the pharynx accounts for bulbar involvement and signs, and extension from the intestinal tract results in affected trunk or extremities. In abortive attacks the process is checked before sufficient anterior horn cells are destroyed to produce paralytic symptoms.

This is a different conception from that formerly held and still adhered to by some that the infection reaches the central nervous system by means of the olfactory tract. Absence of the

virus in the olfactory bulbs contraindicates the nasal tract as the pathway of infection.

This newer conception of the location of the infection in the alimentary tract indicates that preventive measures should be shifted from nasal sprays which as a matter of experience have not proved effective to prevention of infection from contaminated food and drink. Insect vectors in the contamination of food become a possibility. Swimming in pools possibly contaminated by sewage should be avoided.

In the past there has been no definite or generally accepted idea of the manner in which poliomyelitis is transmitted. Alimentary tract transmission perhaps best explains the slight and scattered incidence commonly in evidence with this disease and indicates the likelihood of person-to-person contagion from one with an acute or abortive infection or from one who is a carrier.

THE CENTENARY OF THE FIRST USE OF ETHER ANESTHESIA IN A SURGICAL OPERATION

MARCH 30, 1942, marks the centenary of the first use of ether anesthesia in a surgical operation. It is fitting that the anniversary of this important event should not go unnoticed.

Humphrey Davy in 1800 suggested that nitrous oxide might be capable of destroying physical pain. Michael Faraday in 1818 wrote concerning the anesthetic properties of ether. Chloroform was discovered in 1831 by Guthrie, who called it by the rather startling name of "sweet whiskey." John D. Godman pointed out twenty years before Dr. Long that inhalation of ether vapor could produce anesthesia.

"Laughing gas" parties and "ether frolics" were a popular form of amusement in the early years of the nineteenth century. Among those who indulged in these ether frolics was Dr. Crawford Williamson Long, a graduate of the University of Pennsylvania, who was practicing in his native State of Georgia. In some of the parties held in his office, he noted that he and others who inhaled ether staggered, fell, but felt no pain from their bruises.

One of his acquaintances, James M. Venables, had frequently inhaled ether for its exhilarating effect. He had two tumors on the back of his neck and wanted Long to cut them off. The

operation took place on March 30, 1842, in Long's office. The doctor poured some ether on a towel and the patient inhaled the ether. Long excised the tumor and when Venables awoke, he did not believe that the mass had been removed until it was shown to him. Long wrote in his ledger: "James Venables, 1842, ether and excision tumors \$2.00."

Long wrote his first article on the subject of anesthesia in December, 1849, five years after Wells' demonstration of the anesthetic value of nitrous oxide, and three years after Morton's use of ether anesthesia in Boston. There is no question but that Morton, Wells and Jackson should be given credit for advancing the use of anesthesia. An important attribute of a discoverer is that he be able to recognize and advance his discovery, which, sad to say, Long did not do. However, it is to the honor of Long's memory that the trail of greed, scandal and tragedy that followed Morton, Wells and Jackson did not follow him.

The question of priority in any medical discovery is always uncertain and distasteful. No claim has been made that Long was the actual discoverer of ether anesthesia. However, he was the first to make a successful application thereof in surgery. It is for this that we honor his memory today.

CHARLES E. REA.

RECOMMENDATIONS TO ALL PHYSICIANS WITH REFERENCE TO THE NATIONAL EMERGENCY

I. Medical Students

A. All students holding letters of acceptance from the Dean for admission to medical colleges and freshmen and sophomores of good academic standing in medical colleges should present letters or have letters presented for them by their deans to their local boards of the Selective Service System. This step is necessary in order to be considered for deferment in Class II-A as a medical student. If local boards classify such students in Class I-A, they should immediately notify their deans and if necessary exercise their rights of appeal to the Board of Appeals. If, after exhausting such rights of appeal, further consideration is necessary, request for further appeal may be made to the State Director and if necessary to the National Director of the Selective Service System. These officers have the power to take appeals to the President.

B. Those junior and senior students who are disqualified physically for commissions are to be recommended for deferment to local boards by their deans. These students should enroll with the Procurement and Assignment Service for other assignment.

C. All junior and senior students in good standing in medical schools, who have not done so, should apply immediately for commission in the Army or the Navy. This commission is in the grade of Second Lieutenant,

Medical Administrative Corps of the Army of the United States, or Ensign H.V. (P) of the United States Navy Reserve, the choice as to Army or Navy being entirely voluntary. Applications for commission in the Army should be made to the Corps Area Surgeon of the Corps Area in which the applicant resides and applications for commission in the Navy should be made to the Commandant of the Naval District in which the applicant resides. Medical R.O.T.C. students should continue as before with a view of obtaining commissions as First Lieutenants, Medical Corps, upon graduation. Students who hold commissions, while the commissions are in force, come under the jurisdiction of the Army and Navy authorities and are not subject to induction under the Selective Service Acts. The Army and Navy authorities will defer calling these officers to active duty until they have completed their medical education and at least 12 months of internship.

II. Recent Graduates

Upon successful completion of the medical college course, every individual holding commission as a Second Lieutenant, Medical Administrative Corps, Army of the United States, should make immediate application to the Adjutant General, United States Army, Washington, D. C., for appointment as First Lieutenant, Medical Corps, Army of the United States. Every individual holding commission as Ensign H.V. (P), U. S. Navy Reserve, should make immediate application to the Commandant of his Naval District for commission as Lieutenant (J.G.) Medical Corps Reserve, U. S. Navy. If appointment is desired in the grade of Lieutenant (J.G.) in the regular Medical Corps of the U. S. Navy, application should be made to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

III. Twelve Months Interns

All interns should apply for a commission as First Lieutenant, Medical Corps, Army of the United States, or as Lieutenant (J.G.), United States Navy or Navy Reserve. Upon completion of twelve months internship, except in rare instances where the necessity of continuation as a member of the staff or as a resident can be defended by the institution, all who are physically fit may be required to enter military service. Those commissioned may then expect to enter military service in their professional capacity as medical officers; those who failed to apply for commission are liable for military service under the Selective Service Acts.

IV. Hospital Staff Members

Interns with more than twelve months of internship, assistant residents, fellows, residents, junior staff members, and staff members under the age of forty-five, fall within the provisions of the Selective Service Acts which provide that all men between the ages of twenty and forty-five are liable for military service. All such men holding Army commissions are subject to call at any time and only *temporary deferment* is possible, upon approval of the application made by the institution to the Adjutant General of the United States Army certifying that the individual is temporarily indispensable. All such men holding Naval Reserve commissions are subject to call at any time at the discretion of the Secretary of the Navy. Temporary deferments may be granted only upon approval of applications made to the Surgeon General of the Navy.

All men in this category who do not hold commissions should enroll with the Procurement and Assignment Service. The Procurement and Assignment Service under the Executive Order of the President is charged with the proper distribution of medical personnel for military, governmental, industrial, and civil agencies of the entire country. All those so enrolled whose services have not been established as essential in their present capacities will be certified as available

to the Army, Navy, governmental, industrial, or civil agencies requiring their services for the duration of the war.

V. All Physicians Under Forty-five

All male physicians in this category are liable for military service and those who do not hold commissions are subject to induction under the Selective Service Acts. In order that their service may be utilized in a professional capacity as medical officers, they should be made available for service when needed. Wherever possible, their present positions in civil life should be filled or provisions made for filling their positions, by those who are (a) over forty-five, (b) physicians under forty-five who are physically disqualified for military service, (c) women physicians, and (d) instructors and those engaged in research who do not possess an M.D. degree whose utilization would make available a physician for military service.

Every physician in this age group will be asked to enroll at an early date with the Procurement and Assignment Service. He will be certified for a position commensurate with his professional training and experience as requisitions are placed with the Procurement and Assignment Service by military, governmental, industrial or civil agencies requiring the assistance of those who must be dislocated for the duration of the national emergency.

VI. All Physicians Over Forty-five

All physicians over forty-five will be asked to enroll with the Procurement and Assignment Service at an early date. Those who are essential in their present capacities will be retained and those who are available for assignment to military, governmental, industrial or civil agencies may be asked by the Procurement and Assignment Service to serve those Agencies.

The maximal age for original appointment in the Army of the United States is fifty-five. The maximal age for original appointment in the Naval Reserve is fifty years of age.

* * *

All inquiries concerning The Procurement and Assignment Service should be sent to The Executive Officer, 5654 Social Security Building, 4th and Independence Avenues, S.W., Washington, D. C., and not to individual members of the Directing Board or of committees thereof.

* * *

EDITOR'S NOTE: The above explicit statement of regulations affecting medical students and physicians, has been prepared by the Procurement and Assignment Service and should serve to answer numerous questions which have arisen the past few months.

In Memoriam

John Hultgren Bong

John Hultgren Bong was born in Stockholm, Sweden, the son of Rev. and Mrs. John Bong, July 25, 1872. After the death of his parents he came to America to live with an aunt at Carlton, Minnesota, where he attended high school. He attended Valparaiso University, Valparaiso, Indiana, the University of Minnesota Medical School for three years, and completed his studies at Hamline Medical School, from which he was graduated in 1897. He practiced in Minneapolis until December, 1898, when he located in Jasper, Minnesota.

In 1899 Dr. Bong married Louise L. Johnson, the local druggist. She was the widow of Dr. M. Johnson, a pioneer physician.

He remained in Jasper until 1907 when he went to Chicago for postgraduate study. He remained in Chicago for two years and then located in Reno, Nevada, where he specialized in the treatment of eye, ear, nose and throat. In 1911 he returned to Jasper and resumed practice, remaining until the time of his death, December 13, 1941.

Dr. Bong was in good health up to one week before his death, at which time he contracted an infection in the arm. He was taken to Ashton Memorial Hospital where he died.

In the medical field Dr. Bong held the position of health officer and served as examiner for many insurance companies. He served as mayor of Jasper for over twenty-five years. He was a member of the Southwestern Minnesota Medical Society, the Minnesota State and American Medical Association. He was a member of many fraternal organizations, among them St. Elmo Masonic lodge where he served as Worthy Master, Triune Chapter, Pipestone Comman-

dary, and Osman Temple of the Shrine at Saint Paul, Minnesota. The Masonic lodge had charge of the services which were held in the High School Auditorium December 19, 1941, with burial at Jasper. Dr. Bong is survived by one son, Dr. J. Norman Bong, a dentist of Minneapolis, and his second wife, Emma, whom he married in 1926. Louise Bong, his first wife, died in 1924.

Stephen B. Haessly

Dr. Stephen B. Haessly of Faribault died at St. Mary's Hospital in Rochester, January 11, 1942, following a six weeks' illness.

Dr. Haessly was born December 25, 1875, at Campbellsport, Wisconsin. He received his medical training at the College of Physicians and Surgeons in Chicago, where he graduated in 1904.

Dr. Haessly began practice at Cannon Falls in 1904 and remained there until 1909 when he moved to Red Wing. In 1912, he became associated with Dr. C. A. Traeger in Faribault in the operation of the Central Clinic. His practice was limited to disease of the eye, ear, nose and throat.

Dr. Haessly was a member of the Board of the Tuberculosis Sanatorium at Mineral Springs and was a past president of the staff of St. Lucas Hospital in Faribault. He had been prominent in medical and civic activities in Faribault for thirty years. In May, 1941, he was elected second vice president of the Minnesota State Medical Association. He was a member of the Rice County Medical Society, the Minnesota State and American Medical Associations.

Dr. Haessly is survived by his widow and two sons, Stuart of Minneapolis, and Burdette, now a lieutenant in service at Fort Lewis.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association

George Earl, M.D., Chairman

STATE PROCUREMENT COMMITTEE

DR. W. F. BRAASCH of Rochester has been appointed chairman of the Minnesota Committee which will coöperate with the Procurement and Assignment Service.

The three-fold functions of this committee will be:

1. To secure enrollment of all physicians, beginning with those under 45 who might be available for military service, with the Procurement and Assignment Service.

2. To provide needed information to the Procurement and Assignment Service in regard to qualifications and professional standing of individual physicians in the state.

3. To determine what physicians are rendering services in their present positions which are essential to the public health and welfare and for whom it would be impossible to secure satisfactory substitutes.

Serving on the Committee with Dr. Braasch are the following physicians: Drs. A. N. Collins, Duluth; L. E. Daugherty, Saint Paul; D. A. MacDonald, Minneapolis; G. L. Gosslee, Moorhead; J. A. Thabes, Sr., Brainerd; R. C. Hunt, Fairmont.

PROCUREMENT PROGRAM

Confusion and misunderstanding surrounded early announcements and instructions from the Procurement and Assignment Service.

These misunderstandings have now been ironed out and an integrated military program for all medical men has been worked out in the form of recommendations to all physicians with reference to the national emergency by the board and its executive officer, Major Sam F. Seeley.

Here are the recommendations in abbreviated form:

For Students

1. All students holding letters of acceptance for admission to medical colleges, as well as all

freshmen and sophomores in good standing, should present letters to that effect to local boards of the Selective Service System for classification in Class II-A. If, in spite of the letters, the boards classify them in I-A, they should immediately notify their deans and if necessary appeal, first to the Board of Appeals, then to the state and national directors of Selective Service and, finally, through the regular routine provided for the purpose to the President.

2. All junior and senior students in good standing should apply immediately for commissions in the Army or Navy to the Corps Area Surgeon or to the Commandant of the Navy district in which the applicant resides. They will be commissioned as Second Lieutenants of the Medical Administrative Corps of the Army or as Ensigns in the United States Navy Reserve, according to their own choice. While they hold such commissions they will not be subject to induction under the Selective Service Act, and will be deferred until they have completed their education and twelve months of internship. Medical R.O.T.C. students should continue as before with a view to obtaining commissions as First Lieutenants in the Medical Corps upon graduation. Juniors and seniors who are disqualified physically are to be recommended for deferment to local boards by their deans. These students should enroll with the Procurement and Assignment Service for other assignments.

For Interns

3. Recent graduates and interns who hold commissions as Second Lieutenants should immediately apply to the Adjutant General, United States Army, Washington, D. C., for appointment as First Lieutenants, and Ensigns should apply to the Commandants of their Naval Districts for commissions as Lieutenants in the Navy Medical Corps Reserve or to the Bureau of Medicine and Surgery, Navy Department, Washington, for commissions as Lieutenants in the regular

Medical Corps of the United States Navy. Those who fail to make their applications run the risk of being inducted into service as enlisted men.

4. Interns, residents, fellows and junior staff members up to the age of 45 are subject to call. If they hold commissions only temporary deferment is possible if they can show they are temporarily indispensable. If they do not hold commissions they should enroll at once with the Procurement and Assignment Service which is charged by the president with proper distribution of medical personnel for military, governmental, industrial and civil agencies of the entire country. If they are not established as essential in their present capacities, they will be certified as available to appropriate agencies for the duration of the war.

For Physicians Under Forty-five

5. All male physicians under forty-five are now liable for service and those who do not hold commissions are subject to induction under the Selective Service Act. All will be asked to enroll at an early date with the Procurement and Assignment Service, and there they will be certified for positions commensurate with their professional training and experience and assigned in accordance with requisitions made by military, governmental, industrial or civil agencies. Wherever possible these men should make provisions for filling their present positions by men over forty-five or by men who are physically disqualified for military service or by women physicians, instructors or in some cases, by research workers who do not possess M.D. degrees but who could make available a physician for military service.

6. All physicians over forty-five will be asked to enroll with the Service at an early date. Those who are available may be asked to serve in military, governmental, industrial or civil agencies at a later date.

NOTE: *The form for enrollment with the Procurement Service published by "The Journal of the American Medical Association" to all members last month has been withdrawn. A new form to replace it will be ready shortly for publication and distribution.*

Twenty-one—Thirty-five

It should be understood that the Procurement Service is not likely to be in operation in time to

aid physicians from twenty-one to thirty-five (the original draft ages). These men are now being called for induction under the Selective Service Act as rapidly as possible. All who have not already applied for commissions are likely to be inducted as enlisted men unless their local draft boards are willing to defer them pending an application, after they are called, for commission. Many draft boards refuse to grant deferments for commission unless the applicant has already applied before his number was called.

NOW THERE ARE NINE

The famous four freedoms became nine freedoms in the recommendations recently transmitted by the President to Congress for post-war America. The nine were drawn up by the National Resources and Planning Board, the President said, and among them, as was to be expected, was "the right to adequate food, clothing, shelter and medical care."

As a matter of fact, there is every reason to believe that plans are already formulated in Washington for a full-dress government medical service as an expansion of the Social Security program whenever Congress and the times seem ripe for it.

More Government Participation Likely

In his message on expansion of Social Security the President mentioned hospitalization especially, as an objective to be sought in changing Social Security at this time. Informed officials appear to doubt that Congress will act on this recommendation soon. But the civilian dislocation and hardship — greater probably than anyone foresees now — that will follow in the wake of the acute war emergency will inevitably call for greater and greater government participation in every department of life.

That has been the course of history in other countries and there is little reason to believe that we shall escape it here.

British Plans

In Britain, for example, a commission representing many elements in official life including, of course, the British Medical Association, is even now working on a plan for wartime and post-wartime expansion of their system of panel practice. There is much talk among planners of scrapping the entire system and putting medi-

cine, like the Civil Service, completely under control of the state. The doctors appear to prefer extension of the present system and to fear for patient-physician relationships under a civil service of medicine. But nobody, not even the B.M.A., appears to blench at the thought of State Medicine.

How far the trend will go in America depends, of course, upon how actively American elements opposed to paternalism, fight it and also upon how far the private system can be shown to have failed.

For Free Enterprise

It is ironic, however, that one of the nine freedoms proposed by the National Planning Board should hold a serious threat to free medical service; that this right which appears in the published list as No. 3 should be followed in position No. 5 by the right "to live in a system of free enterprise."

Perhaps the most ironic item of all the nine is the last, which is "the right to rest, recreation and *adventure*." Does the Planning Board envision an Office of Adventure and a young American so bound around by its rights and freedoms and benefits that adventure will be dead and only a wise and benevolent government can be relied upon to provide romance for its young?

Anyway, here they are as quoted in the newspapers:

1. The right to work.
2. The right to fair pay, adequate to command the necessities and amenities of life.
3. The right to adequate food, clothing, shelter and medical care.
4. The right to security, with freedom from fear of old age, want, dependency, sickness, unemployment and accident.
5. The right to live in a system of free enterprise.
6. The right to come and go, to speak or to be silent, free from the spyings of secret political police.
7. The right to equality before the law.
8. The right to education.
9. The right to rest, recreation, and adventure.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

Renville County Mail Carrier Convicted of Criminal Abortion

Re State of Minnesota vs. Fred Wells.

On December 12, 1941, a jury in the District Court of Renville County, Minnesota, returned a verdict of guilty against Fred Wells, sixty-four years of age, the defendant being charged with the crime of abortion. On December 16, 1941, Wells was sentenced by the Honorable Harold Baker, District Judge, to a term of not to exceed two years at hard labor at the State Prison at Stillwater.

Wells, who for more than twenty-five years had been a rural mail carrier, resided at Buffalo Lake, Minnesota. He was arrested on October 13, 1941, following the filing of a complaint against him by Mr. Russell L. Frazee, County Attorney of Renville County. The defendant demanded a preliminary hearing which was held on October 29, 1941, before Justice of the Peace George H. Jacobson at Olivia, Minnesota. At the conclusion of the hearing the defendant was held to the District Court for trial under bond of \$2,000.00. The bond was not furnished and the defendant was remanded to jail. On November 12, 1941, Mr. Frazee filed an information against the defendant charging that on or about January 1, 1940, the defendant performed a criminal abortion on a twenty-four-year-old unmarried girl. The defendant entered a plea of not guilty, and on December 8, 1941, a jury was impanelled and the case proceeded to trial.

Evidence was introduced showing that the defendant, who had no medical education of any kind, attempted to induce a criminal abortion by the use of a small metal can. There was also evidence that the defendant had performed a previous abortion on the same girl at a summer cabin in Stearns County. Before being sentenced, the defendant stated to the Court that he was born at Chippewa Falls, Wisconsin, and had completed the fifth grade in school.

The Minnesota State Board of Medical Examiners wishes to commend Mr. Frazee for the energetic and thorough manner in which he conducted the investigation in this case. These cases are most difficult to try, and the fact that the case was brought to a successful conclusion is a tribute to the able manner in which it was tried by Mr. Frazee.

RESEARCH ON GERM POISONS BRINGS \$1000 AWARD

Studies of the chemical nature of the poisons produced by diphtheria and scarlet fever germs won for Dr. Alwin M. Pappenheimer, Jr., of New York University College of Medicine, the \$1,000 Eli Lilly and Company Research Award in Bacteriology and Immunology, given at the meeting of the Society of American Bacteriologists in Baltimore.

Larger quantities of pure material for making toxoid to protect children against diphtheria is one result of the type of studies Dr. Pappenheimer has made.—*Science News Letter*, January 10, 1942.

INDUSTRIAL HEALTH

Edited by the Committee on Industrial Health and Occupational Diseases

J. L. McLeod, Grand Rapids, Chairman

H. B. Allen, Austin
L. S. Arling, Minneapolis
G. L. Berdez, Duluth

T. G. Clement, Duluth
W. S. Lemon, Rochester
T. A. Lowe, South Saint Paul

O. H. Wangenstein, Minneapolis
A. E. Wilcox, Minneapolis

PROGRAM FOR MINNESOTA

Several members of our committee attended the Fourth Annual Congress on Industrial Health in Chicago, January 12 to 14, 1942. The meetings developed the seriousness of our situation as a nation at the moment and stressed the vital importance of the work done by medicine in keeping the production lines running at full capacity twenty-four hours per day. The defense situation has made necessary many adjustments and changes in the general attitude of the medical profession, toward the health of the worker. Dr. Sam F. Seeley, Executive Officer, Procurement and Assignment Service, pointed out to us that the emergency is much greater than we in the middle west realize. He stated that the army must and will call for several thousand more doctors in all departments for use in army medical service. The biggest call will be for men between 35 and 45 although men up to 60 will be called as needed. All of us must be ready. No one can assume the attitude that he is indispensable where he is should orders call for him elsewhere in the service of his country.

In addition to the direct army requirements, medicine has the tremendous responsibility of keeping up the health of the workers in all defense projects. The enormity of this problem has not yet been brought home to the general public, because even the medical man who should understand it has not seriously considered his responsibility. Defense activities now include every worker in the nation. Even the farmer is on the defense line.

Your committee has consulted informally with Dr. Giffin, and has arrived at the following conclusions respecting work to be encouraged this year. The following specific ideas will be considered and developed:

1. A thorough study of occupational disease in Minnesota. Each of us is about to receive from the State Board of Health special forms to be filled out on all cases of disease which may be associated with a man's occupation so that we may get definite information as to the nature and extent of this problem in Minnesota. We expect your coöperation in this matter.

2. Our committee will contact and work with other groups which have similar interests. Such groups as the safety council, nurses committees, dental committees, and many others will be approached for the purpose of statewide industrial health promotion.

3. It is increasingly evident that all medical schools must give instructions along industrial health lines. With this thought in mind your committee will give consideration to contacting the University in behalf of a definite course of instruction, covering this new medical responsibility. It has been shown that industry has not been able to find medical men who are trained in industrial practice. To correct this trouble special training must be developed.

J. LAWRENCE MCLEOD

NOTES FROM THE CHICAGO MEETING

Physiologist A. C. Ivy of Northwestern University cautioned against the seven-day week with long hours in our urgent war industries because lowered productivity may be the result. The British have found a fifty-six-hour week for men and a forty-eight-hour week for women gives their maximum output. Longer hours may be harmless if work is not heavy and physical fitness is maintained. Emotional strain, staleness, rest periods, working habits, economic factors, vacations and one day's rest in seven, must all be considered.

* * *

Lack of industrial training opportunities in our medical schools was regarded as serious by a score of men well known in the industrial field. Every recognized medical school with any reasonable material available for industrial teaching was urged to take steps toward correction of this deficiency. (The University of Minnesota is surrounded by industries of 500 or more employes which could readily become the source of clinical material. War demands on personnel may prevent development of these possibilities until after World War II.)

* * *

Health education for industrial workers was discussed by Dr. Everett D. Bristol. He stressed simplicity, clarity in all information presented through articles in newspapers, in motion pictures, payroll inserts, posters, displays and on the radio. Best results are obtained, he said, by direct health instruction to small groups and by repetition.

* * *

Ear plugs made of vaseline and cotton or commercially made plugs are valuable for civilians subjected to bombing raids and for airplane mechanics or pilots, as well as for workers subjected to any other excessive noise. The noise of an airplane motor striking the eardrums can be reduced with vaseline-cotton plugs to the volume of a busy street noise.

Heat sickness was also discussed.*

*A page on prevention and management of heat sickness in an industrial plant will appear here before our hot weather begins.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCASTS FOR FEBRUARY

The Minnesota State Medical Association broadcasts weekly at 10:45 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Director of Postgraduate Medical Education, Medical School, University of Minnesota.

February 7—Hemorrhage and Shock

February 14—First Aid in Fractures

February 21—Treatment of Wounds

February 28—Injuries of Jaw and Teeth

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

The American Association of Industrial Physicians and Surgeons, and the American Industrial Hygiene Association will hold their joint Annual Convention in Cincinnati from April 13 to 17, 1942. A program is in preparation in which important medical and hygienic problems associated with the present huge task of American industry will be presented and discussed in clinics, lectures, symposia, and scientific exhibits. The central purpose of the meeting will be to provide a five-day institute for the interchange and dissemination of information on new problems as well as for the consideration of up-to-date methods of dealing with those that are well known. The industrial physicians have taken responsibility for the program of the first two and one-half days and the hygienists for the remainder of the five days, but most of the subjects chosen for discussion will be of interest not only to physicians, but equally so to industrial engineers, and executives.

AMERICAN COLLEGE OF SURGEONS

Because of the war, the thirty-second annual Clinical Congress of the American College of Surgeons will be held in Chicago, October 19 to 23, instead of in Los Angeles as originally planned. Headquarters will be at the Stevens Hotel. The twenty-fifth annual Hospital Standardization Conference sponsored by the College will be held simultaneously. The programs of both meetings will be based chiefly on wartime activities as they affect surgeons and hospital personnel in military and civilian service.

LABORATORY WORK

In accordance with the recommendations and agreements of the State Serological Committee (syphilologists and clinical pathologists), a plan for the interlaboratory checking of blood specimens with serodiagnostic tests for syphilis has been adopted. This procedure has been conducted during the past two years and has

proved to be of benefit to participating laboratories in improving the efficiency of such work.

It was agreed that the Division of Preventable Diseases, Minnesota Department of Health, should assist by supplying blood specimens from a carefully selected group of syphilitic donors to those laboratories which do not have available such specimens for testing. It was also agreed that a member of the Laboratory Staff of the Division should visit the laboratories to discuss problems arising in relation to the work and to give advice and assistance as desired. Workers in other laboratories are cordially invited to visit the Division of Preventable Disease Laboratories for the purpose of observation and study of methods used. Blood specimens may be sent by the participating laboratories for checking through special study. Many of the laboratories in the state are taking part in this study. An effort has been made to contact all the laboratories which employ one or more serodiagnostic tests for syphilis in the case of donors or patients or both; however, it is probable that there are some which have not been located.

Further information regarding participation in these studies may be obtained by writing to the Division of Preventable Diseases, Minnesota Department of Health, University Campus, Minneapolis.

—A. J. CHESLEY,
Executive Officer

JOHN W. BELL LECTURE

Dr. William H. Feldman, a member of the Staff of the Institute of Experimental Medicine, of the Mayo Foundation, graduate school, University of Minnesota, will deliver the Eighth Annual John W. Bell Tuberculosis Lecture to the Hennepin County Medical Society on February 2, at 8:00 p.m., in the Medical Society Rooms, Medical Arts Building. The Lecture is sponsored by the Hennepin County Tuberculosis Association. Dr. Feldman's subject will be "Chemotherapy of Experimental Tuberculosis."

Members of the Committee on Arrangements in behalf of the Lecture are: Dr. H. S. Diehl, Chairman of the Committee, Dr. Stephen H. Baxter, ex officio, President of the Hennepin County Tuberculosis Association, Dr. E. J. Huenekens, President of the Hennepin County Medical Society, Dr. F. E. Harrington, and Dr. M. J. Shapiro.

MEDICAL COURSE AT MINNESOTA ACCELERATED

Acceleration of the medical course at the University of Minnesota so that a student will graduate from the Medical School in three calendar years after his admission is one of the several changes adopted by the Medical School with the approval of the Board of Regents.

The acceleration will be accomplished by starting the

next class at the beginning of the summer session and by omitting summer vacations.

Increasing the enrollment in the Freshman Class to 125 is another major change.

These two actions will result in making available to the armed forces an increased number of physicians, and will make them available three to twelve months earlier than if the present schedule were continued. The accelerated curriculum and increased enrollment will be discontinued at the end of the war.

Likewise, the executive faculty has also decided to: Discontinue comprehensive examinations during the war. Under the present system of comprehensive examinations a student who fails to pass them in the spring may take them again in the fall and, if he passes, go on without loss of time. Elimination of vacations would make it necessary for a student who failed in his examinations to wait at least nine months before going on with the work of the next year. For that reason they are being replaced by course examinations.

Install a new Junior-Senior curriculum which spreads the lectures ordinarily concentrated in the Junior year and the clinical work ordinarily concentrated during the Senior year, more evenly over both years. This is intended to be permanent.

PROTEIN SEMINARS AT UNIVERSITY OF MINNESOTA

The Department of Physiology, University of Minnesota Medical School, has organized a series of twenty seminars on the Structure and Behavior of the Proteins. Experts from numerous departments within the University and several from other institutions are leading the discussions.

The increasing importance of knowledge about proteins in the virus, enzyme and blood protein fields has made this seminar series important and well attended by the staff members and graduate students of the University. The meetings are held in Room 15, Medical Sciences Building. The remaining Seminar topics follow:

- February 5—"Double Refraction in Proteins"—Dr. W. Heller
- February 19—"X-Ray Diffraction Studies in Crystalline Proteins"—Dr. L. Fankuchen
- February 26—"X-Ray Diffraction Studies in Virus Proteins"—Dr. L. Fankuchen
- March 5—"Fundamental Studies of Allergens"—Prof. H. A. Abramson of Columbia University, New York City
- March 12—"Virus Protein Studies"—Professor M. H. Roepke
- March 19—"Plant Protein Studies"—Professor R. A. Gortner
- March 26—"Interaction of Proteins in Solution and at Surfaces"—Professor L. S. Moyer

MINNESOTA PATHOLOGICAL SOCIETY

The program for the February meeting of the Minnesota Pathological Society to be held at the University of Minnesota Medical School at 8 p.m., February 17, will include the following papers:

"Genesis of Gastric and Duodenal Ulcer with Experimental and Clinical Studies" by Dr. O. H. Wangenstein, head of the department of surgery.

"Pathologic Changes in the Gastric Mucosa in Association with Gastric and Duodenal Ulcer" by Dr. Robert

Hebbel of the department of pathology.

BLUE EARTH COUNTY MEDICAL SOCIETY

Dr. H. B. Troost of Mankato was elected president of the Blue Earth County Medical Society at its annual business session, December 29, in Mankato. Dr. J. C. Vezina of Mapleton was elected vice president, and Dr. A. G. Liedloff of Mankato was named secretary and treasurer.

UPPER MISSISSIPPI MEDICAL SOCIETY

Meeting in Brainerd, January 10, the Upper Mississippi Medical Society elected Dr. E. G. Hubin of Deerwood president to succeed Dr. J. P. Hawkinson of Crosby.

Other officers named were: Dr. D. H. Garlock, Bemidji, first vice president; Dr. D. L. Johnson, Little Falls, second vice president; Dr. Glen Leemhuis, McGregor, third vice president; and Dr. G. I. Badeaux, Brainerd, secretary-treasurer.

WASECA COUNTY MEDICAL SOCIETY

Members of the Waseca County Medical Society, holding their annual meeting in Waseca, January 6, elected Dr. Clifford Wadd of Janesville president for the ensuing year. He succeeds Dr. R. O. Spittler of New Richland.

Dr. H. M. McIntire of Waseca was elected vice president, and Dr. George Olds, Waseca, was renamed secretary-treasurer.

WINONA COUNTY MEDICAL SOCIETY

Dr. George L. Loomis of Winona is the newly elected president of the Winona County Medical Society, succeeding Dr. H. W. Satterlee of Lewiston.

Other officers elected at the annual meeting of the society, January 5, in Winona are: Dr. H. J. Roemer, vice president; Dr. John A. Tweedy, secretary; and Dr. R. H. Wilson, treasurer.

Dr. H. O. McPheeters of Minneapolis gave a paper on "The Treatment of Varicose Veins and Ulcers."

About forty persons attended the joint dinner of the medical society and auxiliary at the hotel preceding separate meetings of the two groups.

WASHINGTON COUNTY

At the regular monthly meeting January 13, 1942, the scientific program consisted of two colored films on surgery. One was titled Sub-total Gastrectomy for Perforating Duodenal Ulcer, taken at the Lahey Clinic, Boston, and one Vaginal Repair of Cystocele and Rectocele by Dr. Arthur H. Curtis, Northwestern University Medical School. These two films furnished an enjoyable and profitable evening for the members.

The question of vaccination in this county came up for serious consideration. It was decided that every effort should be made to have all the children in the city and rural schools vaccinated and the school boards and teachers were to be approached to give all assist-

WOMAN'S AUXILIARY

ance possible in this matter. Besides that, posters, talks, and articles in the papers will be used as media to further convince the people that now, right now, we are in much need of this protection.

SIXTEENTH ANNUAL MEETING NATIONAL CONFERENCE ON MEDICAL SERVICE*

Sunday, February 15, 1942

Program

Morning Session—9:00 a.m.

Registration

1. THE RELATION OF THE PHYSICIAN TO MILITARY, CIVILIAN AND INDUSTRIAL HEALTH
 - (1) Procurement and Assignment of Physicians for Military Service
SAM F. SEELEY, M.D., Executive Officer, Procurement and Assignment Service, Washington, D. C.
 - (2) Civilian Defense
 - (a) Civilian
 - (b) Hospitals
 - (c) Emergency Medical Squads
GRAHAM L. DAVIS, Hospital Consultant, W. K. Kellogg Foundation, Battle Creek, Michigan
 - (3) Industry's Problem in Maintaining Adequate Medical Care
 - (a) Non-Defense Projects
JOHN R. NILSSON, M.D., Chief Surgeon, Union Pacific Railroad, Omaha, Nebraska (Tentative)
 - (b) National Defense Projects
W. D. NORWOOD, M.D., Medical Director, DuPont Company, Elwood Ordinance Plant, Joliet, Illinois (Tentative)
2. THE ROLE OF THE STATE MEDICAL SOCIETY AND STATE AND CITY DEPARTMENTS OF HEALTH IN NATIONAL DEFENSE
 - (1) State Medical Society
W. P. WHERRY, M.D., President Nebraska State Medical Society, Omaha, Nebraska
 - (2) State Department of Health
W. L. BIERRING, M.D., State Health Officer of Iowa, Des Moines, Iowa (Tentative)
 - (3) City Department of Health
HERMAN N. BUNDESEN, M.D., President, Board of Health, Chicago, Illinois

Dinner—12:15 p.m.

Afternoon Session—1:30 p.m.

3. PRESIDENT'S ADDRESS—HAROLD M. CAMP, M.D., Monmouth, Illinois
4. REPORT OF NOMINATING COMMITTEE; ANNUAL ELECTION OF OFFICERS; SELECTION OF PLACE FOR 1943 MEETING
5. REJECTED SELECTEES AND THEIR REHABILITATION FOR ACTIVE MILITARY SERVICE
 - (1) Local and Induction Board Examinations
SAMUEL J. KOPETZKY, M.D., New York City (Tentative)
 - (2) One Million Rejected; What Per Cent May Be Salvaged:

- (a) By Personal Physician or Dentist Prior to Induction
GEORGE BAEHR, M.D., New York City (Tentative)
J. R. BLAYNEY, D.D.S., Chicago, Illinois
- (b) Following Induction
L. D. REDWAY, M.D., Ossining, New York (Tentative)

6. THE ROLE OF THE MEDICAL, DENTAL, NURSING SCHOOLS AND HOSPITALS IN ANTICIPATING THE ACCELERATION OF TRAINING
 - (1) The Need for a Trained Personnel to Care for the Health of the Military
J. R. DARNALL, M.D., Lt. Colonel, Medical Corps, Washington, D. C.
 - (2) Status of Pre-Medic, Medic and Dental Students, Internships and Residencies During the Emergency
LEONARD ROWNTREE, M.D., Chief, Medical Division, Selective Service System, Washington, D. C. (Tentative)
 - (3) What the Medical, Dental and Nursing Schools May Do to Hasten the Graduation of Their Respective Students
FRED C. ZAPFEE, M.D., Chicago, Illinois (Tentative)

WOMAN'S AUXILIARY

MRS. JOHN J. RYAN, *President*
Saint Paul, Minnesota

MRS. L. R. BOIES, *Publicity Chairman*
Knollwood, Hopkins, Minnesota

OUR ROLE IN DEFENSE

Now that war is a reality, we, no doubt, hear many say—"What can I do for Defense?" And all around us, we see a general scrambling, grasping for something, we know not what, which is very confusing.

Let us pause for a moment and "take stock" so to speak, of our own activities. All or most of us have definite home responsibilities which we cannot and should not ignore. Our Defense begins there.

First, let us promote emotional stability and good morale by our positive, "make-the-best-of-it" attitudes.

Restrictions may be inconvenient, but somehow nothing ever becomes too bad, and we still have everything to be thankful for in this great country of ours. Let us be alert regarding instructions given us for emergencies, and coöperate in every way possible, so that we will be prepared.

Food in safeguarding health is as important as it has always been—wholesome, balanced meals mean healthy bodies and beings. Thousands of women are attending Red Cross nutrition classes, learning what to eat, and how to feed people for proper nutrition. Plan simple, nourishing meals for your family. Eliminate wastefulness, and utilize or cut down on leftovers. Speaking of conservation, watching unnecessary lights will reduce your electric bill. You can conserve on heat. Do you take good care of your equipment—in fact, of everything—to make it last longer? We have a fine opportunity to learn a good lesson in thrift today.

Remember, too, your tendency toward hoarding may
(Continued on Page 148)

IN POST-ENCEPHALITIC PARKINSONISM

In post-encephalitic parkinsonism, Bazedrine Sulfate Tablets will often produce marked symptomatic improvement—especially when administered in conjunction with the usual doses of hyoscine, stramonium or atropine.

With this combined therapy, drowsiness, muscular rigidity and tremor, lowered mood, salivation and oculogyric crises can often be controlled or eliminated.

NORMAL DOSAGE: 20 to 40 mg. daily. One-half of the dose at breakfast and the other half at noon. In exceptional cases, larger doses may be necessary.

Bazedrine Sulfate should be used with caution in hypertensive cases and should not be used in coronary disease and other cardiac conditions in which vasoconstrictors are contraindicated. Atropine, stramonium and scopolamine enhance its pressor effect.

Bazedrine Sulfate Tablets are now manufactured in two sizes. In writing prescriptions please be sure to specify the tablet-size desired, either 5 mg. or 10 mg.

BENZEDRINE SULFATE TABLETS

(Continued from Page 146)

bring about more restrictive buying in certain household commodities and, eventually, rationing. Be patriotic by *not hoarding*.

Let us be able to say to ourselves—"I am doing a good job of Defense at home by promoting emotional stability and good morale, preventing wastefulness by conserving and not hoarding, feeding my family properly and simply."

In addition, some of us may still be able to assist in national protection and defense through civic service outside the home.

The task of war can be shortened by your and my cooperation and concentration in concerted action!

COUNTY NEWS

East Central

The East Central Auxiliary met December 4, with Mrs. Gray at Cambridge. Mrs. A. B. Roehlke, Elk River, presided. It was decided to do Red Cross knitting at each meeting. A drive to put *Hygeia* magazine in more schools, offices, and libraries, was to be undertaken. New chairmen appointments were Mrs. W. P. Gardner, Anoka, *Hygeia*, and Mrs. Gordon Tesch, Elk River, Publicity.

Ramsey

The November meeting of Ramsey County Auxiliary was held at the home of Mrs. Phillip C. Roy, 327 Woodlawn. Dr. W. A. O'Brien, University of Minnesota, in his usual genial manner, talked on Nutrition. Mrs. Carol Brink, authoress of several children's books, spoke on that subject. Later, tea was served.

Philanthropic Tea.—It must be said that Ramsey County Auxiliary certainly is foresighted—yes, and very ambitious, to put on their philanthropic project so closely following the holidays.

On Sunday, January 11, a beautiful and well-attended Silver Tea for Philanthropy was held at the home of Dr. and Mrs. Harry B. Zimmermann, 1530 Edgcombe Road, Saint Paul. Seven hundred invitations, to all members of the Ramsey County Medical Society and their wives, were issued. Mrs. Bernard E. O'Reilly was general chairman for the event. Those in charge of invitations were: Mmes. Harold F. Flanagan, Joseph Ryan, A. A. Kugler, H. J. Prendergast. Mmes. Robert Grau and F. W. Lynch were responsible for table arrangements; Mrs. N. P. Bentley for patronesses; the dining room was taken care of by Mmes. Joseph N. Gehlen, G. E. Harmon, R. T. Muller, B. B. Souster, E. R. Steiner, C. R. Tift, Charles W. Wass, and James V. Watson. Hostesses included Mrs. Mark E. Ryan, President of the Auxiliary, Mmes. C. K. Williams, Eugene Scott and C. L. Cain.

The following honored guests and former presidents poured tea: Mmes. H. P. Ritchie, Frank E. Burch, E. C. Eshelby, Edward Schons, A. G. Schulze, E. M. Hammes, Arnold Schwyzer, W. H. Hengstler, W. C. Carroll, E. V. Goltz, Asa M. Johnson, E. H. Bohland, John J. Ryan, A. E. Nichols, George Earl, C. Harry Ghent, and L. G. Dack.

It was a grand success!

Mower

In October, the Mower County Auxiliary met for a 1:30 dessert luncheon. Reports on the State Auxiliary Board meeting held in St. Paul were given by Mmes. C. C. Allen and C. L. Sheedy who had attended. A talk on Nutrition was presented by Mrs. L. G. Flanagan. For the remainder of the afternoon, Red Cross sewing was done.

"Current Medical Legislation" was the subject of the talk given by Mrs. J. G. W. Havens at the November meeting of the Auxiliary at the home of Mrs. James Morrow, 808 So. Kenwood Ave., Austin. This was preceded by dessert luncheon. After the business meeting, the usual Red Cross sewing was done.

Hennepin

The Philanthropic Committee, of which Mrs. F. L. Gilles is chairman, with the help of volunteer auxiliary women must have been super sales people at the annual sale of Glen Lake Sanatorium handwork, at Dayton's in November. The proceeds that are returned to the patients who made the articles netted a record sum. The articles included needlework, carving, embroidered linens and knitted articles. Other members of the committee were: Mmes. F. J. Anderson, K. J. St. Cyr, Harold Leland, K. W. Anderson, Moses Barron, Myron Lysne, E. S. Mariette, Fred Erb.

At the December meeting of the Auxiliary, a Silver Tea was held at the Medical Lounge for Sarahurst, a rehabilitation home for former patients of Glen Lake. Enough money was collected to buy a new chair for the Hennepin County Auxiliary room at the home, and to present five dollar gift certificates, together with some handkerchiefs, to each of the three women occupants. In addition, it was possible to give to each of the five men at the home a crisp one dollar bill.

The program included the reading of "Mother of the Smiths" by the popular Mrs. Roy Jones, and Christmas songs by the Auxiliary Octet.

Tea chairman and hostesses were: Mmes. Carl Laymon, A. E. McDonald, and J. R. Peterson.

The loyalty and enthusiasm of the members of the Auxiliary can certainly not be minimized. For, the day after New Year's, in addition to being a very cold day, eighty-six women attended the January luncheon meeting at 510 Groveland.

Mrs. J. C. Giere, an accomplished pianist, and member of the Auxiliary, presented some beautiful piano selections. Mrs. Viola Thompson, Activities Chairman of the Junior Red Cross, told of her work. Mrs. R. L. Wilder had charge of the luncheon, and Mmes. J. M. Hall and Horace Newhart, acted as hostesses.

The Consumers' Guide, Department of Agriculture publication, says, "You usually have to drink two cups of tomato juice to get as much *vitamin C* as you get from one cup of orange juice. But of course you want to figure costs per cup, too."—*Science News Letter*, January 24, 1942.

BORN of the BLITZ

... New Proof of Life Saving Value of
CORAMINE*

As London underwent its terrible bombing ordeal of last year, the resuscitating value of CORAMINE, "Ciba" was again dramatically proven. As noted by Charles Hill, Deputy Secretary of the British Medical Association, CORAMINE "is being used more and more for those suffering from heart failure."** First aid posts, mobile units, field and base hospitals are equipped with CORAMINE for speedy stimulation of failing cardiac and respiratory systems.

CORAMINE has also been cited for distinguished therapeutic service in accident cases, asphyxia, poisoning, "shock," drowning, pneumonia crises, etc.

ONLY CIBA MANUFACTURES CORAMINE
AMPULES • LIQUID

*Trade Mark Reg. U. S. Pat. Off. Ward "Coramine" identifies the product as the diethyl amide of nicotinic acid of Ciba's manufacture.

Attention is called to the national Victory Book Campaign to collect books for the use of soldiers, sailors and marines at their service posts. The army and

navy libraries are popular but require expansion. Fiction, biography, travel, history and informational books of all types are needed. The campaign is on and will continue until the end of April, 1942. Every public library in the country will be used as a collection center and books to be donated may be taken to the libraries. Miss Ruth H. Rosholt, Minneapolis Public Library, is State Director of the Campaign, which is sponsored by the Red Cross, the United Service Organizations and the American Library Association.

* * *

The United States General Hospital No. 26, composed of fifty University of Minnesota physicians, seven dentists and 120 nurses, will be mobilized for active service, February 15, it is announced.

Word of the mobilization was received from the United States Surgeon's General's office by Dr. L. H. Fowler, head surgeon and commander of the unit.

The group, which is to be augmented by 500 enlisted men from the Army, will be sent to Fort Sill, Oklahoma, to undergo a training course of two or three months. After completion of training, the unit is expected to be sent overseas.

Honoring members of the hospital unit, the University of Minnesota will entertain at a farewell dinner, February 10, in Coffman Memorial Union. University faculty members and the general public are invited.

Dr. Joseph Borg, assistant professor of medicine, is in charge of the unit's medical service; Miss Cecelia H. Hauge, in charge of nurses.

Presentation of the Parke-Davis Hospital Day Publicity Cup and Plaque to the Glenwood Community Hospital was an event of December 9.

The plaque was presented at a dinner meeting at Glenwood, which 175 persons attended. Dr. William A. O'Brien of the University of Minnesota Medical School was the guest speaker. Among representatives of organizations who extended congratulations to the Glenwood Hospital were A. M. Calvin, executive secretary of the Minnesota Hospital Service Association; Dr. Walter Gardner, president-elect of the Minnesota Hospital Association; and Victor Anderson, chairman of the Council on Administrative Practice.

Miss Dina Bremness, R.N., is superintendent of the hospital, which won the cup by virtue of staging the best publicity campaign for Hospital Day of any hospital in the United States and Canada in cities of 15,000 people or less. Two such awards were made, one for those in cities over 15,000 and one for those in cities under that size.

* * *

A number of gifts for medical research were recently accepted by the University of Minnesota Board of Regents. They include:

\$7,000 from the Citizens' Aid Society to support research on the problem of gastric ulcer under Dr. O. H. Wengensteen, to be used over a two-year period.

\$4,700 from the National Research Council for research on fat metabolism.

\$2,500 from the National Confectioners Association for use by Dr. Ancel Keys in his study on diet and fatigue.

\$2,000 from the John and Mary R. Markle Foundation, a supplementary grant to support Dr. Albert V. Stoesser's studies regarding water-electrolyte metabolism in intractable asthma.

\$1,200 from the W. H. Barber Co. for the Sivertsen Foundation for Cancer Research.

\$1,000 from an anonymous donor through the Minnesota Medical Foundation to establish a research problem in the division of Internal Medicine.

* * *

The first certificate in the Minnesota Tuberculosis Control Program was presented to Lincoln County, December 11, at a special ceremony held at Tyler.

Dr. B. J. Branton, Willmar, president of the Minnesota State Medical Association, presented the certificate of accreditation signed by Governor Stassen to M. L. Anderson of Canby, chairman of the Lincoln board of county commissioners.

The Tuberculosis Control program is a coöperative campaign of the State Association and the State Department of Health to accredit counties showing a tuberculosis mortality rate not to exceed ten per hundred thousand of population and an incidence of tuberculous infection among seniors in high school not to exceed 15 per cent. The mortality rate must be based on a five-year average and the student rate on tests of at least 80 per cent of the senior students of the county. The program is believed to be the first adopted for tuberculosis control in a human population and is patterned after the federal plan to accredit areas showing eradication of tuberculosis in cattle.

A PRIMER ON THE PREVENTION OF DEFORMITY IN CHILDHOOD. Richard Beverly Raney, B.A., M.D. Associate in Orthopaedic Surgery, Duke University School of Medicine, Durham, N. C., and Attending Orthopaedic Surgeon, Watts Hospital, Durham, N. C. In collaboration with Alfred Rives Shands, Jr., B.A., M.D. Medical Director, Alfred I. du Pont Institute of The Nemours Foundation, Wilmington, Del.; Visiting Professor of Orthopaedic Surgery, University of Pennsylvania School of Medicine, Philadelphia. 188 pages. Illus. Price, \$1.00, cloth. Elyria, Ohio: National Society for Crippled Children, Inc., 1941.

AN INTRODUCTION TO DERMATOLOGY. Richard L. Sutton, and Richard L. Sutton, Jr. 4th ed. \$9.00. 904 Pages. Illus. St. Louis: C. V. Mosby, 1941.

Sutton and Sutton's Introduction to Dermatology is an abbreviation of the larger book, Diseases of the Skin by the same authors. It is now presented in the fourth edition since 1932. This so-called introduction mentions almost every disease of the skin described in medical literature. Many diseases, particularly the more common ones, are well described. However, discussions of some of the less common diseases are so short and inadequate that one would have difficulty recognizing the disease from the description. The avowed purpose of the book might have been as well served by omission of consideration of these rare dermatoses.

Any classification of diseases of the skin is necessarily confused. However, it seems unnecessary, according to the present concept of the seborrheal dermatoses, to consider seborrhea and seborrheal dermatoses under

PROFESSIONAL PROTECTION

A DOCTOR SAYS:

THE

MEDICAL PROTECTIVE COMPANY

OF

FORT WAYNE, INDIANA

separate headings in different parts of the book. The subject of pemphigus might have been better handled. The discussion of the classification of lichen chronicus simplex is clear and helpful.

In discussing treatment of the various dermatoses the authors list almost every type of therapy, including the new developments such as the sulfonamide compounds. While this is common practice in texts on dermatology, it leaves the uninitiated with no clear idea of where to start in handling a given case. The authors continue to expound at length on the treatment of acne and seborrhea by reducing the fat intake and by the administration of thyroid, forms of therapy which have not been found successful by the majority of practitioners.

There are numerous good illustrations taken from the Suttons' book, *Diseases of the Skin*. No colored plates are included.

LAWRENCE M. NELSON, M.D.

COMMUNICABLE DISEASE CONTROL: A Volume for the Health Officer and Public Health Nurse. Gaylord W. Anderson, A.B., M.D., Professor and Head of the Department of Preventive Medicine and Public Health, University of Minnesota; Formerly Deputy Commissioner and Director of the Division of Communicable Diseases, Massachusetts Department of Public Health; and Margaret G. Arnstein, R.N., M.A., M.P.H., District Supervising Nurse, New York State Department of Health; Formerly Associate Professor of Preventive Medicine and Public Health and Director of the Course in Public Health Nursing, University of Minnesota. New York: The Macmillan Company, 1941. 434 pages. Price, \$4.25, cloth.

The older philosophy that in order to be effective the pill must be bitter, has been carried over into the compounding of all too many medical treatises. Accordingly, the yearning for a text which at one and the same time is comprehensive but not meticulous, precise though not pedantic, systematic as a log table yet, withal, readable as a novel, has prompted many to reflect, "Some day, I'm going to write a book!" Here is such a book, within the field of communicable disease control, well worth the reading time of any physician or nurse. For the health officer, in full or part time work, this textbook will prove delightfully useful. The authors modestly state, "An attempt has been made to

evaluate the various control measures as to their relative effectiveness and to outline programs that will yield the greatest return in terms of necessary expenditure." The "attempt" has succeeded.

MARIO FISCHER, M.D.

SYNOPSIS OF APPLIED PATHOLOGICAL CHEMISTRY. Jerome E. Andes, M.S., Ph.D., M.D., F.A.C.P., and A. G. Eaton, B.S., M.A., Ph.D., 427 pages. Illus. Price, \$4.00, cloth. St. Louis: C. V. Mosby Co., 1941.

This book might best be described as a five-minute source of abbreviated information on nearly all pathological chemistry having some practical value in clinical medicine. It would find its best application as a quick reference source for a busy physician who can make good use of the hospital chemical laboratory.

There are a few procedures of practical importance which might well have been included such as the recent work on laboratory manifestations of shock and hemorrhage. Occasional errors in judgment of value of work in the literature such as a reference to low serum calcium as being the cause of a hemorrhagic dyscrasia and the omission of the important theory of lowered blood volume as an explanation of extrarenal azotemia are noted. A frank error is made in the statement that low blood uric acid values eliminate the possibility of gout. Nevertheless the book fills a needed place in the library of physicians who have the ability to combine clinical observations and interpretations of accurate measurements of physiological processes to arrive at a diagnosis.

ARTHUR H. WELLS.

TYPHOID DEATHS OF SEVENTY-EIGHT CITIES LOWEST SINCE 1910

Typhoid death reported in 1940 of 78 U. S. cities surveyed since 1910 were only 172, the lowest number on record. So reports the *Journal, American Medical Association* (January 17) on the basis of the 1940 census plus information from city health officers.

The *Journal* reports the rate for all cities as now "just about one-half of one point per hundred thousand of population." No typhoid outbreaks have been recorded.—*Science News Letter*, January 24, 1942.

Benzedrine Sulfate

in Mild Depressions

THE PHYSICIAN in general practice, as well as the specialist, encounters many patients suffering from mild depressions. With such patients, there is ample evidence in the literature that Benzedrine Sulfate therapy will often produce some or all of the following effects:

- (a) Increased mental activity and interest.
- (b) Optimism, cheerfulness, euphoria, increased self-assurance and sense of well-being.
- (c) Psychomotor stimulation; increased interest, motor activity and accessibility.
- (d) Increased feeling of energy and alertness; increased capacity for physical and mental effort.

In many patients, depression may occur as an accompaniment of some more fundamental pathology, either organic or psychogenic. In such cases, the physician should bear in mind that while Benzedrine Sulfate will not affect the underlying condition, its stimulatory effects may help to alleviate the depression which so often interferes with the management of the case. It is primarily useful in depressions characterized by apathy and psychomotor retardation, but is contraindicated in patients manifesting anxiety.

The use of Benzedrine Sulfate by normals should not be permitted; it should always be administered under the careful supervision of a physician; and depressive psychopathic cases should be institutionalized.

In treating depressed patients with Benzedrine Sulfate, the physician should bear in mind that any drug which produces pleasant or euphoric effects may prove to be habit forming—especially in unstable or neurotic individuals.

SMITH, KLINE & FRENCH LABORATORIES

PHILADELPHIA, PA. — ESTABLISHED 1841

THROUGHOUT the life of G-E electromedical equipment, there is a factory-trained representative ready to give immediate service—a friend for life, nearby.

It's his job to make the rounds of hospitals and physicians and respond to their emergency calls for technical service or advice on the operation and maintenance of G-E x-ray or physical therapy apparatus, electrocardiographs and fever therapy equipment—all highly technical in design and operation.

WE'VE MADE IT MORE *Convenient* AND
Economical TO USE *Amniotin...*

THERE'S little question about the effectiveness of Amniotin in relieving menopausal symptoms . . . that's been proved by a great number of clinical reports published during the past twelve years. Amniotin has also proved effective in other conditions related to deficiency of estrogenic hormone . . . senile vaginitis . . . kraurosis vulvae . . . pruritus vulvae . . . gonorrheal vaginitis in children.

Important to users of estrogens is the fact that Amniotin is now available in 10-cc. and 20-cc. diaphragm-capped vials. These new "bulk packages" provide two advantages . . . economy and convenience. The wide variation in requirements of women with menopausal symptoms can be met by simply withdrawing the proper dosage from the vial. The new vial packages provide a substantial saving over the cost of Amniotin in ampuls . . . without sacrifice of activity, uniformity or stability.

Differing from estrogenic substances containing or derived from a single crystalline factor, Amniotin is a highly purified, non-crystalline preparation of naturally occurring estrogenic substances derived from pregnant mares' urine. Its estrogenic activity is expressed in terms of the equivalent of International units of estrone.

HOW SUPPLIED

A SQUIBB PREPARATION OF ESTROGENIC SUBSTANCES
 OBTAINED FROM THE URINE OF PREGNANT MARES

Q. When I serve a dish of canned peas or spinach or some other canned vegetable to a patient, how can I know how much ascorbic acid the patient is getting?

A. I couldn't assign a definite numerical value. All vegetables have an upper and lower limit of ascorbic acid content. This probably is also true for their other essential nutrients. The ascorbic acid content of a given sample is determined by a number of factors, like variety, state of maturity when picked, soil, weather, and what happens to the vegetable between the time it is harvested and served to the patient. It is very likely that canned vegetables are fully equal in ascorbic acid content to kitchen-prepared vegetables. I suggest you be guided by reliable publications on the ranges of vitamin contents in canned foods. (1)

Pneumonia deaths will continue to decrease steadily with this most promising Sulfonamide...

SULFADIAZINE

Lederle

THE VALUE OF SULFAPYRIDINE AND SULFATHIAZOLE in the treatment of pneumococcal pneumonias has been impressively demonstrated by extensive clinical use. Sulfadiazine, the newest of the famous sulfonamide family, shows even greater promise. The ideal sulfonamide would be flexible in its method of administration, non-toxic to the host, devoid of sensitivity effects and would be therapeutically active against a wide range of common infecting agents. Although a perfect sulfonamide is unlikely of attainment, it is believed that sulfadiazine possesses distinct advantages in the treatment of certain conditions. CECIL¹ has expressed the opinion that clinically sulfadiazine is the best of the antipneumococcal drugs.

Recently clinical workers² have confirmed the results of earlier investigators³ that sulfadiazine is equal in therapeutic efficiency to sulfapyridine or sulfathiazole in the treatment of pneumococcal pneumonia; is rapidly absorbed from the gastro-intestinal tract; the blood levels obtained are usually higher than with comparable doses of sulfapyridine and sulfathiazole; and excretion takes place slowly. All these factors coupled with the *infrequency of nausea and vomiting* tend to reassure both patient and physician.

Experimentally⁴ sulfadiazine has been shown to compare favorably with sulfanilamide in its action against streptococci. The excellent therapeutic activity of the drug against experimental⁵ hemolytic streptococcal and Friedlander's bacillus Type B infections has encouraged the clinical trial of sulfadiazine in these infections.

BIOLAC is complete and replete...

...because there is no lack in Biolac, except for vitamin C. Biolac feeding provides amply for all other nutritional requirements of the normal young infant, and no additional formula ingredients or supplements are necessary. It's an improved evaporated-type infant food with breast-like nutritional and digestional advantages. It is a complete formula, replete with nutritional values. Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrates of vitamins A

and D from cod liver oil, and ferric citrate.

Why BIOLAC is an ideal infant formula food:

- Ample provision for high protein needs of early months
- Reduced fat level for greater ease in digestion
- Enriched with vitamins A, B₁, D and iron
- All needed carbohydrate in the form of Lactose
- Sterilized for formula safety
- Homogenized to improve digestibility
- Easy to prescribe
- Convenient for mothers to use
- Economical: nothing need be added

Prescribe Biolac in your next feeding case. Professional literature on request. Write Borden's Prescription Products Division, 350 Madison Ave., New York, N. Y.

Borden's BIOLAC

A BORDEN PRESCRIPTION PRODUCT

SHOCK ABSORBER

Theelin acts as a therapeutic cushion to help absorb the physical and mental shocks so often caused by ovarian hypofunction during the menopause. Theelin accomplishes this by replacing or supplementing declining ovarian secretion until such time as the endocrine system can adjust itself to the hormonal deficiency. Its clinical reputation is firmly established on the basis of millions of doses successfully used. Indications: the climacteric, senile vaginitis, kraurosis vulvae, gonorrheal vaginitis in children, and certain other conditions due to estrogenic insufficiency. Theelin was the first estrogen to be isolated in pure crystalline form. Each lot is physiologically and chemically standardized before release by the laboratories of Parke, Davis & Company and by the Biochemical Laboratory of St. Louis University. Theelin Suppositories for vaginal use and Kapseals Theelol for oral administration are available where sustained therapy between injections is desired.

Polyps of nasal cavity

Shrinkage after application of Neo-Synephrin Hydrochloride

PATHOLOGY OF THE UPPER RESPIRATORY TRACT: I

Nasal Polyps

SOLUTION

EMULSION

JELLY

The great majority of upper respiratory diseases are characterized by the acutely distressing symptom of nasal congestion. Both for subjective relief and improvement of drainage, shrinking of the mucous membranes may be indicated.

NEO-SYNEPHRIN HYDROCHLORIDE

(laevo-alpha-hydroxy-beta-methyl-amino-3 hydroxy ethylbenzene hydrochloride)

a potent synthetic vasoconstrictor—relieves congestion rapidly, without sting, with more prolonged effect than ephedrine and with lower toxicity in therapeutic dosage. Unpleasant side effects are rare.

DOSAGE FORMS:

SOLUTION— $\frac{1}{4}\%$ and 1% in saline solution (1-oz. bottles)
 $\frac{1}{4}\%$ in Ringer's solution with Aromatics (1 oz.)

EMULSION— $\frac{1}{4}\%$ (1-oz. bottle with dropper)

JELLY — $\frac{1}{2}\%$ (in collapsible tubes with nasal applicator)

These are the Reasons why we say "Try S-M-A"

- Physicians will find that S-M-A* is not a "compromise formula." It is a complete milk formula for infants deprived of human milk.
- Cows' milk fat is replaced with the unique S-M-A fat for easy digestion and adequate nutrition. It compares physically, chemically and biologically with the fat in human milk.
- The carbohydrates in S-M-A and human milk are identical.
- With the exception of vitamin C, the vitamins essential to normal growth and development (B₁, D, and A) are included in adequate proportion in S-M-A ready to feed.
- Furthermore, iron (so difficult to provide for the bottle-fed infant) is included in S-M-A. When prepared each quart provides 10 mg. iron and ammonium citrate.

* * * * *

Excellent results with hundreds of thousands of infants is reason enough why S-M-A is the choice of a steadily increasing number of physicians.

Try S-M-A. Results tell the true story more aptly than words and pictures.

*S-M-A, a trade mark of S.M.A. Corporation, for its brand of food especially prepared for infant feeding—derived from tuberculin-tested cow's milk, the fat of which is replaced by animal and vegetable fats, including biologically tested cod liver oil; with the addition of milk sugar and potassium

chloride; altogether forming an antirachitic food. When diluted according to directions, it is essentially similar to human milk in percentages of protein, fat, carbohydrate and ash, in chemical constants of the fat and physical properties.

RACÉPHEDRINE HYDROCHLORIDE

(UPJOHN)

With the winter come colds and upper respiratory infections. To relieve the resulting nasal congestion, you will again need a reliable decongestant.

Racéphedrine Hydrochloride (Upjohn) is available as a 1% solution in Modified Ringer's Solution, in one ounce dropper bottles for prescription purposes, and in pint bottles for office use.

Fine Pharmaceuticals Since 1886

The art of doing things well

IN THE Lilly Laboratories not just any cat or frog that happens along is used in standardizing digitalis. Lilly accuracy demands careful selection and housing of test animals under standard conditions in order to avoid individual variations due to environment and nutrition. Frogs which are being prepared for digitalis testing are held in a constant temperature bath where a variation of no more than 0.1°C . is permitted. The results of testing are evaluated by competent workers, some with over twenty years of experience in digitalis standardization.

UNDULANT FEVER

D. G. MAHLE, M.D.

Plainview, Minnesota

UNDULANT fever is also known as Malta fever, Gibraltar, Mediterranean, Neopolitan, Cyprus, or Danube fever, Bruce's septicemia, goat fever, slow fever, and mountain fever.

It is stated that this disease was recognized by Hippocrates. Under the name of remittent malarial fever, it is said to have been described by Burnett in 1914. Until recent years undulant fever was unrecognized outside of the Island of Malta and the countries bordering upon the Mediterranean Sea.

The cause of undulant fever was discovered in 1887 by Bruce, a British army officer, stationed on the Island of Malta, and for whom the organism, a small coccobacillus, *Brucella melitensis*, has been named. In 1897 Wright and Semple brought into use the agglutination method of diagnosis. This method has since proved a valuable aid to the diagnosis of undulant fever. In 1904-1907, a British Commission, headed by Bruce, found the goat of Malta to be a "natural reservoir" of infection.

In 1905, Craig, a U. S. Army Officer, recorded the first human case recognized as originating in the United States. The patient, a nurse, in Washington, D. C., had had no association with goats. Similar reports were later made in France, England, Egypt, and elsewhere, diagnosis being confirmed by the agglutination test.

In Arizona and Texas numerous brucella infections have been reported in goat herds and in consumers of goats' milk since 1911, and in 1922 in Arizona there was an epidemic of 83 cases among consumers of goats' milk.

In 1918 Evans found the organisms of contagious abortion in cattle and hogs to be indistin-

guishable culturally from *Brucella melitensis* from goats, shown by Bruce to be the cause of undulant or Malta fever in man.

In 1924 Keefer reported in Baltimore the first human case of undulant fever proved to be due to the organism causing contagious abortion in cattle.

In 1926 Carpenter reported five cases of undulant fever in which *Brucella melitensis*, abortus type, was found. Two of these patients had been consuming cows' milk which was shown to be infected with the contagious abortion organism, i.e., *Brucella melitensis*, abortus type. Since 1926, human cases traceable to the abortus type of *Brucella melitensis* have been reported from a large number of states throughout the country. Bruce defined Malta fever as "a disease of long duration, characterized clinically by continued fever, profuse perspiration, constipation, frequent relapses, rheumatic or neuralgic pains, swelling of joints, or orchitis; bacteriologically by the presence in the blood of organisms of *Micrococcus melitensis* [now *Brucella melitensis*]; anatomically by congestion of the spleen and other organs."

The disease, a bacteremia or septicemia with an incubation period of two weeks or less, may present varying clinical pictures. The undulating character of the fever, when present, is often striking, but some cases present only prolonged fever with marked irregularities. The illness may be acute, subacute, or chronic. Ambulant cases frequently occur. There is abundant evidence that infection may take place without producing noticeable symptoms. The symptoms vary widely in severity and duration; the joints and the nervous system are frequently affected; the blood often shows moderate anemia with leukopenia and fre-

President's address at the seventy-third annual meeting of the Wabasha County Medical Society, Wabasha, Minnesota, October 21, 1941.

quently an increase in the number of mononuclear leukocytes. The disease is rarely fatal. Recurrences are frequent and the disease may be continuously or intermittently present over a period of months and, in some instances, years.

In the four cases which I wish to present, practically all of the symptoms mentioned were present to some degree in one or the other of the patients. In the first case, seen on May 19, 1938, the presenting complaints were weakness, pain in the back, headache, pain in the eyes, loss of appetite, and chills. The symptoms were first noted three weeks before and upon consulting a physician at that time he was told he had "the flu and was nervous." After this the symptoms abated gradually only to recur two weeks later. The first symptom noted was headache and a severe pain in the eyes, especially when he moved them from side to side. He felt best as a rule in the morning but as the day wore on, the fever, chills, and sweating became more prominent until it reached its climax at bedtime. He could work only for short periods at a time because of weakness and he had a marked loss of appetite.

Clinically the man appeared normal except for his apprehension. He had a temperature of 102.4 degrees; his pulse rate was 92 per minute. The leukocyte count was 7,950 with about 56 per cent lymphocytes. The tuberculin test was negative. His blood serum agglutinated the antigen used by a local veterinarian in testing for Bang's disease in cattle in a dilution of 1:200. According to the State Board of Health the agglutination titer was 1:640.

In the second case the presenting complaints were weakness, fever, chills, excessive sweating, and loss of appetite. Here, too, the fever and chills came on toward evening with marked sweating at night, the symptoms having been present for about three weeks. He had not paid much attention to the symptoms because he felt pretty well otherwise. He had no aches or pains. However on the day of examination, March 25, 1939, he became so weak he had to go to bed. He also suffered a complete loss of appetite the same day.

Clinically he too appeared normal. He had a temperature of 102.6 degrees. His hemoglobin test was 80 per cent. The tuberculin test was negative. His agglutination titer using the same Bang's antigen was 1:400. According to the State Board of Health, it was 1:160.

The third patient, seen January 29, 1940, complained of weakness, fever, and lack of appetite. He went on to explain how he had had "flu" three weeks previously and had never really recovered. He was too weak to do his work and he had a very poor appetite.

Clinically this man too did not appear particularly ill and there were no abnormal findings. He had a temperature of 100 degrees and a pulse rate of 88 beats per minute. A tuberculin test was done. Two days later when seen at his home he had a painful right wrist and heel and a painful, slightly swollen left testicle. His temperature at this time was 103 degrees, the leukocyte count was 9,850. The tuberculin test was negative. Urinalysis revealed nothing unusual. His agglutination titer for *Brucella melitensis* according to the State Board of Health was 1:1280.

The fourth patient, seen on August 25, 1941, gave as his presenting complaints headache, fever, chilly sensations, and slight loss of appetite. For two weeks he had had the above symptoms. The headaches seemed associated with a stiff and painful neck. He thought he had a fever at times, especially in the afternoons and evenings. He stated that he became chilled easily on cool evenings. He worked hard all the time during threshing season but he felt more like lying down than working. However, he was not sick enough to go to bed. His appetite was not as good as usual and he thought he had lost a little weight.

This man was rather nervous and apprehensive but aside from that no unusual clinical signs were found. He weighed 157 pounds, which was about seven pounds less than his usual weight. His temperature was 99.2 degrees and his pulse 76 beats per minute. His blood pressure was 130 systolic and 84 diastolic. His hemoglobin was 86 per cent; his leukocyte count 7,100. The tuberculin test was negative. A sedimentation test showed a rate of 4 mm. the first half hour, 18 mm. in one hour, 38 mm. in 1.5 hours, and 51 mm. in two hours. The agglutination titer to *Brucella melitensis* according to the State Board of Health was 1:320.

The enlarged spleen mentioned as common in this disease was found in none of these cases, no doubt largely because I recall rarely ever having been able to palpate an enlarged spleen in any disease.

In Minnesota, 1,023 cases of undulant fever were reported from March 11, 1927, to January

1, 1941. In addition, one case was reported in a transient and sixty-four in nonresidents.

Of these 1,023 cases, 798 were in males with seventeen deaths, and 225 were in females with six deaths. This indicates a death rate of approximately 2 per cent. The greatest number of cases—more than half—occurred between the ages of twenty-five and forty-five years. Incidentally, the ages of my cases were thirty-three, twenty-eight, thirty-five, and thirty-nine years respectively. They were all males and farmers. Of the total cases in Minnesota during this time about a quarter were farmers, another quarter were housewives, domestics, and packing plant employes. The remaining half were of a large variety of occupations.

The first patient I mentioned began to drink a considerable amount of milk about three months before becoming ill, because he thought it would be good for him. Upon testing his herd he found that four of his milk cows were infected. The second patient had always consumed large amounts of raw milk. When he tested his herd, he found sixteen milk cows and two heifers infected.

The last two patients both had handled Bang's-infected material. One had handled material about two months before his first noticeable symptoms. While it was found that he had a clean herd himself, he had helped his neighbor "clean" three cows that had aborted. When the neighbor tested, he found nine reactors. As a result of this test eleven other farmers in the immediate vicinity tested but fortunately no other positive reactors were found. The last case, under treatment at the present time, had "cleaned" one of his own cows two weeks before he became ill. He has not tested his cattle to date but no doubt he will find reactors because he has had trouble with abortion in his herd.

It is interesting to note that of the total cases reported, 658 gave raw milk as the probable source of infection, although 198 of these were farmers and had also handled abortion material. Ninety-one gave handling of abortion material as the source of infection and 177 had handled meat in packing plants. The remainder gave various sources of infection.

Various forms of vaccines, chemicals, and fever therapy have been tried in the treatment of this disease at first with indefinite results, but more recently with definite beneficial effects. Dr.

L. E. Prickman of the Mayo Clinic has been treating cases of undulant fever with artificial fever therapy and in 1938 he stated approximately 80 per cent of the patients were relieved. At present he is continuing with the same form of treatment and has had the same fine results with some forty or more cases. He gives from one to three treatments with a temperature of 105 to 107 degrees, each treatment lasting from four to five hours.

In recent years, sulfanilamide has been used with varying degrees of success. Welch, Wentworth, and Mickle of Hartford, Connecticut, in 1938 reported sulfanilamide "a valuable therapeutic aid in treatment of this disease," based on an experience of five cases. They also used sulfanilamide diagnostically because it increased the cytophagic activity of the blood for brucella organisms.

Blumgart of Boston the same year reported rapid recovery of one case and recommended its further trial. He also listed similar experiences of others who had tried this type of treatment. He included one report by Groues in which he had used successfully sulfanilamide in combination with vaccine in eight cases.

Drs. Trout and Logan of Chicago and Oak Park, Illinois, reported "prompt and apparently permanent cures in two cases with brucellosis," this too in 1938. However, Carey of Detroit reported in 1940 no apparent benefits in three pediatrics cases using the drug.

In my own experience, sulfanilamide was used in three cases in doses ranging from 75 to 25 grains a day. In all three instances the temperature returned to normal and the patients felt much improved within four or five days of the onset of treatment. In addition to the sulfanilamide, I used Lederles *Brucella melitensis* vaccine containing 2,000,000 heat-killed organisms per c.c. My theory in using the vaccine is that in a disease which has a tendency toward chronicity and recurrences, it is desirable to increase the resistance of the patient to the causative organism as much as possible. Certainly this can do no harm and may give the patient a more lasting protection than the use of the drug alone.

I understand that Dr. Harris of New York, who lives in a community where there is a great deal of brucellosis, and has had a very wide experience with the disease, recently has published

a book on "Brucellosis." In it he is very enthusiastic about vaccine therapy, using the heat-killed organisms, and preferring this form of treatment above all others.

I give the vaccine in doses starting with 0.25 c.c. every three or four days, gradually increasing the amount until 1 c.c. is given. This amount is continued until about 10 c.c. have been used. There is usually some local and general reaction with the first few doses, lasting for about a day. My first patient, treated in 1938, was given this vaccine alone. His recovery was prolonged somewhat, although his temperature remained normal after seven days until about one month after treatment was begun, when he had fever reactions following the last two injections. These were discontinued and he made a complete and uneventful recovery.

There have been no recurrences in any of these cases, although one is still under treatment at the present time. He is feeling fine and doing more of his work all the time. His weight has returned to 160 pounds, which is his usual weight. His sedimentation test now shows 4 mm. the first half hour; 15 mm. the second; 26 mm. the third; and 38 mm. the fourth. He is still taking the vaccine treatment and this may account for the sedimentation test not having returned to normal. Incidentally this patient is the only one of the four who had a positive blood culture for the organisms. In this case the blood was taken for culture during a fever reaction and before starting treatment. These conditions were not met in any of the other cases.

There are two things essential in the control of this disease. The first has to do with the care of the herd and is the farmer's responsibility. Bang's abortion disease in cattle results in serious financial losses to dairymen and breeders through loss of calves, sterility of cows, and consequent lessened milk production. Therefore, intelligent breeders and dairymen in increasing numbers are seeking to free their herds of contagious abortion.

In Olmsted county since 1927 there have been ten cases of undulant fever reported. Up until 1939 only 27.6 per cent of herds were Bang's tested. In Winona County there have been fourteen cases reported since 1927. Three of these were cases presented tonight occurring in White-water township. Until 1939 29.9 per cent of herds had been tested for Bang's disease. In Wabasha County, there were twelve cases reported,

the case reported tonight from Elgin township not included. In our county only 23.2 per cent of the herds had been Bang's tested up to 1939.

The State Livestock Sanitary Board offers co-operation to dairy farmers and breeders. Plans making it possible to have abortion-free herds may be obtained by writing directly to the State Live Stock Sanitary Board, State Office Building, Saint Paul.

The second essential in the control of this disease has to do with milk and is the responsibility of the consumer. The organisms which cause undulant fever in human beings and contagious abortion in cattle, hogs, and goats, are readily killed by heat. Through the pasteurization of goats' milk, undulant fever was reduced in Malta from 643 cases in 1905 to one case in 1910. Through the pasteurization or boiling of cows' milk, all danger of human infection from this source is eliminated. Therefore, if the milk does not come from an accredited herd, the consumer must insist on pasteurization or boil his milk.

Conclusion

1. A brief history of the origin and distribution of undulant fever has been given with particular emphasis upon Minnesota and our own and adjacent counties.

2. The symptoms and characteristics of the disease have been described in brief.

3. Four personally observed and treated cases were reported with cures and no recurrences to date.

4. Of the various forms of treatment advocated for this disease, artificial fever therapy, and sulfanilamide plus vaccine therapy seem to offer the most consistently favorable results.

5. Two things essential in the control of the disease are Bang's testing of all cattle, and pasteurization or boiling of all milk.

6. I wish to acknowledge the help and co-operation of Dr. L. E. Prickman of the Mayo Clinic, and the Minnesota Department of Health in supplying material and references for this paper.

MARKED RETRUSION OF THE MANDIBLE

GORDON B. NEW, M.D., and JOHN B. ERICH, M.D.

Rochester, Minnesota

IT is not possible to arrive at a satisfactory and comprehensive notion of the therapeutic problems that arise in the care of patients with severe mandibular retrusion without first reviewing the methods which have been advocated for the treatment of such deformities. Briefly, in accordance with the degree of retrusion, these defects may be divided into three groups: (1) minor defects in which the recession of the lower jaw is entirely the result of dental malocclusion and which, when they occur among young individuals, may be cured by orthodontic measures; (2) similar defects occurring among patients too old for orthodontic treatment, and also defects of a more advanced nature; and (3) very extreme cases of mandibular retrusion in which the lower jaw is so greatly underdeveloped and displaced so far posteriorly that no type of osteotomy could begin to lengthen or advance the mental portion sufficiently. Defects in the first two groups may be corrected by means of one or a combination of the following methods: (a) various types of osteotomy through the horizontal or ascending rami to lengthen or advance the mandible; (b) cartilage implants inserted behind the head of the condyles for advancement of the mandible; (c) cartilage or bone implants for building up the chin to normal contour. In defects in the third group, cartilage or bone implants for building up the chin to normal contour are of no value as it would be impossible to insert a large enough graft to bring the chin forward into the desired position. In fact, none of the methods of treatment which have been mentioned are applicable here, and, consequently, in presenting a case of marked mandibular retrusion in this paper, it is therapeutic management that we wish to discuss in detail.

The etiologic factors which contribute to a severe mandibular retrusion are osteomyelitis, temporomandibular ankylosis, unreduced fractures of the lower jaw, particularly bilateral subcondylar fractures, and birth injuries. In order to produce extreme mandibular retrusion, these causative factors must occur during the growing period of the individual when the jaws are under-

going a series of changes in development. Not until the patient has reached full maturity, at which time the physiologic processes involved in the development of teeth and bone have been completed, does such a defect reach its final stages. In short, the earlier in life at which an injury occurs to initiate retrusion of the mandible, the more pronounced is the ultimate deformity. Since a retruded mandible is a deformity of progressive severity during the developmental period of the jaws, the sooner treatment can be instituted, the more satisfactory will be the final result.

Severe retrusion of the mandible is characterized by a posterior displacement of the entire lower jaw to such a degree that the lower anterior teeth are often situated as far back as the upper first molar region. Under such circumstances, there is little or no occlusion of teeth, and mastication of food is almost impossible. Frequently, the lower teeth possess a forward inclination, and if the defect has occurred before the upper anterior teeth are fully erupted (an age at which the upper lip is not fully developed), there is a tendency for the upper anterior teeth to protrude also. The deformity is conspicuous externally because of an extreme degree of retrusion of the chin; this may be associated with shortening of the upper lip, asymmetry of the nasolabial sulci, or other marks of facial disharmony.

In the treatment of a markedly retruded mandible, it is our opinion that the most satisfactory results can be obtained by the use of an intra-oral prosthetic appliance for restoration of normal contour of the chin and for establishment of adequate dental occlusion. This procedure has been used by some plastic surgeons both in this country and in England. In the employment of such a prosthetic appliance, it is necessary to bring the lower lip and soft tissues of the chin forward by incising the mucosal attachment of the lower lip to the anterior part of the mandible. Such an incision leaves a large, raw pocket. Before a prosthetic appliance can be inserted into such a pocket, the latter must be lined with skin to prevent subsequent contractures and distortion

From the Section on Laryngology, Oral and Plastic Surgery, Mayo Clinic, Rochester, Minnesota.

of the soft tissues of the chin and lower lip. It is also important that this pocket be extended down around the lower border of the mandible to create an undercut which will aid in the retention of the prosthesis. Since immobilization

ment of the compound-covered frame to the casting a cake of modeling compound is softened in hot water and packed down around the frame into the pocket. When hard, the compound and frame are securely united and together form a

Fig. 1. Appliance for fixation of a skin graft used in lining a pocket between the lower lip and alveolar process for reception of a prosthetic appliance; a, cast silver dental splint as seen from above; b, casting cemented to lower anterior teeth; c, wire frame for holding dental modeling compound around which the skin graft is wrapped; two small screws which anchor the wire frame to the casting also are shown.

is one of the most important factors in successful skin grafting, the problem in lining an intra-oral cavity with a skin graft lies in the difficulty of obtaining adequate fixation of the part during the healing period. We have developed the following technic for maintaining absolute fixation: As a preliminary measure, a silver cast dental splint, which is cemented to the lower teeth, is required (Fig. 1). On the anterior aspect of this casting are two threaded holes into which steel screws may be turned (Fig. 1). A wire frame, which can be securely fastened by the screws to the casting is also constructed (Fig. 1). Following the preparation of the pocket between the lower lip and alveolar process, the wire frame is fixed to the casting and adjusted so as to lie in the center of the wound. It is then removed and coated with a thin layer of dental modeling compound which has been melted in a flame. This compound, softened in this manner, will adhere perfectly to the frame, whereas the compound softened in hot water will not. After re-attach-

Fig. 2. Application of skin graft to dental appliance; a, after packing dental modeling compound around the wire frame (Fig. 1c) and into the intra-oral pocket so as to form a stent for the cavity, a Thiersch skin graft from the inner aspect of the thigh is wrapped about the stent which previously has been coated with rubber cement or mastisol; b, the skin graft is sutured over the upper surface of the stent; c, the stent, covered with the skin graft, is inserted into the intra-oral pocket; this method gives perfect fixation of the graft during the healing period.

ment of the compound-covered frame to the casting a cake of modeling compound is softened in hot water and packed down around the frame into the pocket. When hard, the compound and frame are securely united and together form a stent that is perfectly adapted to all the irregularities of the pocket. On removal from the mouth, the stent is coated with rubber cement or mastisol (a solution of mastic in benzene). A thin Thiersch skin graft (from the inner surface of the thigh), which is cut preliminary to the intra-oral operation, is wrapped about the stent and sutured along its upper surface (Fig. 2). The stent covered with skin graft is then inserted into the pocket and is screwed to the dental casting (Fig. 2). Adhesive plaster applied externally firmly fixes the lower lip to the stent, which is immovable. With the elapse of ten days, the stent may be removed and the pocket will be found to be lined perfectly with skin.

After the intra-oral pocket has been successfully lined with skin, the prosthetic appliance is constructed. This possesses artificial teeth which articulate with the upper teeth, hide the malposed lower teeth and establish a similarity to natural dental occlusion. It is essential that the appliance, which is rather bulky, be hollowed out to reduce its weight. If there are one or more lower posterior teeth on either side of the mandi-

ble, it is well to retain such teeth, even though badly decayed, for fixation, the prosthetic appliance being attached to these teeth by dental clasps. Due to the continuous stress and strain of this appliance, the lower teeth gradually be-

situated as far back as the upper first molar region. This defect was associated with a short, underdeveloped upper lip and extreme protrusion of the upper anterior teeth, which was to be expected in view of the fact that the deformity began at the age of five years. If the etiologic factors which had contributed to this

Fig. 3. Appearance of patient when first observed at the clinic.

Fig. 4. Appearance of patient after correction of the deformity.

come loosened, and eventually must be extracted. However, if they can be retained for a few months until the tendency for the skin-lined pocket to undergo contraction has been overcome, the appliance can then be successfully worn without the use of clasps. For a few days after the appliance has first been inserted, the lower lip, which is stretched and tense, has a tendency to contract downward. To counteract this retraction, adhesive tape must be used to hold the lower lip up in the desired position. As a matter of fact, a period of about six months is required for the muscles of the lower lip to develop sufficiently to maintain the lower lip in a natural position but, after this time has elapsed, the end result is most gratifying from an esthetic point of view.

Report of Case

A woman, aged twenty-nine years, came to the clinic because of a facial deformity in which the lower jaw was markedly retruded (Fig. 3). At the age of five years she had had a dental abscess which had resulted in an extensive osteomyelitis of the mandible. On examination it was found that the chin was practically absent and that the lower jaw was displaced posteriorly to such an extent that the lower anterior teeth were

mandibular retrusion had not occurred until the patient were twelve or thirteen years of age, the upper lip would have been better developed and there would have been much less malposition of the upper dental arch.

The marked protrusion of the upper anterior teeth and alveolar process was considered as much a part of the facial deformity as was the retruded mandible. Consequently, at the time of the plastic operation, all of her upper teeth, which were badly carious, and much of the anterior portion of the upper alveolar process were removed. In addition, the decayed lower teeth were also extracted with the exception of two lower molars that were retained for retention of the prosthetic appliance. A pocket was prepared between the lower lip and jaw and lined with a Thiersch skin graft as has been described. Then a full upper denture and a prosthetic appliance were prepared. This was clasped to the two lower molar teeth fitted into the skin-lined pocket. Both plate and prosthesis were made with artificial teeth which met in normal occlusion. The ultimate result effected by these surgical and mechanical procedures was most satisfactory both esthetically and functionally (Fig. 4). Not only interesting but also significant was the change in this patient's mental attitude after the operation. Preoperatively, her shyness was so extreme that she would converse with no one except members of her immediate family. However, after restoration of her facial contour to normal proportions, there was a remarkable disappearance of her sense of inferiority.

The pictures of patients with tuberculosis in our medical textbooks are those of emaciated and cachectic individuals when they should be those of apparently healthy specimens. It is in these apparently healthy specimens that disease is so often found and causes so much destruction.—A. M. DIETRICH, M.D., *Del. Med. Jour.*, Aug., 1941.

OCULAR MANIFESTATIONS OF HEAD TRAUMAS

THOMAS J. EDWARDS, M.D.

Saint Paul, Minnesota

DUE to the development in mechanization and speed of all our modes of travel and transportation, we are being called upon to see an ever increasing number of eye injuries in accidents involving the head.

An intimate knowledge of the ophthalmic symptoms following head injuries lends considerable aid to the accurate diagnosis of the location and extent of the injury and, although the problem of surgical intervention is primarily that of the neuro-surgeon, we can by recognition and interpretation of the ocular manifestations greatly aid him in this solution.

There is the medico-legal problem which is usually associated with head injuries, where there is an involvement of vision or function of the eyes, which demands a very careful ocular examination to determine the extent of eye involvement and to exclude malingering.

The investigations of Rawlings⁴ have shown the tendency of most fractures of the skull to converge toward the pituitary region. The symptoms listed in the accompanying table assist in the location of the fracture.

It is a general rule that the earlier the occurrence of eye symptoms follow cerebral injuries, the more serious is the injury.

Blakeslee¹ has shown in his report from the Harlem Hospital neurological service that in 610 cases of skull fracture, 416 (78 per cent) showed eye manifestations. These included:

1. Ecchymosis and hemorrhage in the lid, conjunctiva or orbit.
2. Damage to the optic nerve.
3. Fundus change.
4. Nystagmus.
5. Pupillary irregularities.
6. Paralysis of extra-ocular muscles.

Emphysema is exceedingly common in head injuries, occurring most frequently from fractures of the lamina papyracea and is by itself no cause for alarm. It usually subsides readily following application of a compression bandage.

Hemorrhage of the lids and conjunctiva is of fairly common occurrence, being seen in 106 of the 610 cases, most often unilateral. The mechanism of production is thought to be extravasation along the nerve sheath and penetration of Tenon's capsule, or by direct extension into the orbital tissue through fracture of the roof of the orbit. The presence of hemorrhage involving the eyes should lead one to suspect a fracture, even though it could not be demonstrated by roentgenology.

The intra-ocular changes most often seen consist of hemorrhage and choked discs. The hemorrhage may be retinal, subhyaloid or vitreous. In Wolff's anatomy⁶ a diagram of the blood supply of the optic nerve illustrates how a stasis of the ciliary veins and the circle of Zinn causes a break through the lamina cribrosa and hemorrhage into the retina and vitreous. This mechan-

ism has also been well described by Derrick Vail of Cincinnati.

With the occurrence of a subarachnoid hemorrhage there is often found a quite typical retinosis, consisting of hemorrhage around the disc, which may be severe enough to extend well out into the vitreous or which may be confined to the retinal layer. These may be accompanied by choked discs.

New-born infants are frequently found on routine examination to have retinal hemorrhages which later clear up without leaving any damage to the retina. These are thought to be due to head trauma received in passage through the birth canal.

A similar picture may be seen in subdural hematoma, and the case of a three-month-old infant admitted to the pediatric service of the University Hospital who was accidentally dropped by her mother illustrates this. The child vomited and had two convulsions soon after the accident. Spinal tap showed increased spinal pressure and a bloody fluid. The anterior fontanelle was bulging and all reflexes were hyperactive. The fundi showed a mild elevation of the optic nerve with blurred margins and numerous punctate and flame-shaped hemorrhages, retinal and subhyaloid. A ventricular tap was done and clear fluid removed. A cisternal tap showed no evidence of communication of the subdural space and the cisternal fluid. Repeated subdural taps were made every two or three days over a period of two months until the anterior fontanelles were shrunken and then a craniotomy was done. An organized mass was found and removed. The fundi cleared without any damage to vision.

The occurrence of papilledema is quite common, especially in cases of subdural hemorrhage. Its presence with the history of head injury indicates, as a rule, hemorrhage, either subdural, extradural or intracerebral, with increased intracranial pressure. Kearney states that if all individuals with head injury were examined immediately after the accident a great percentage would be found to have a mild edema of the disc and a venous engorgement. This may be transitory. As a rule, the onset of a choked disc is about three to eight days, and it may persist for only a short time or last for years.

Injuries to the anterior portion of the frontal lobe rarely produce papilledema. Injuries to the cerebral hemispheres may produce moderate

edema while involvement of the posterior fossa, with blockage of the foramen magnum, may produce a very marked edema.

One must also bear in mind the possibility that a hemorrhage along the nerve sheath with compression of the vessels may produce stasis and papilledema. The neurosurgeons feel that the presence of a papilledema is an indication for the necessity of a decompression procedure or an exploratory operation.

Injuries to the optic nerve may take place at the intracranial, intracanal, orbital or papillary portions. The intracranial or short portion extending back from the optic canal to the chiasm may be compressed by fracture of the sphenoid and also from basal bleeding. There have been a few cases reported in which the optic nerve was completely torn from the chiasm.

Injuries in the canal occur mainly from fractures of the walls of the optic foramen by which the optic nerve is either primarily lacerated or compressed or secondarily compressed through bleeding.

The optic nerve from its entrance into the canal is covered by a connective tissue sheath, a prolongation of the dura, and lined by the arachnoid and pia. These are intimately connected except for lymph spaces. The dura is connected closely to the upper walls of the canal, while laterally and downward it is more loosely attached by connective tissue fibers so that in cases of partial injury to the nerve the visual field usually shows a contraction in the upper half as the clot and pressure is confined to the lower part of the canal.

While it is not possible to definitely fix the lesion in life, so many cases at autopsy have shown the injury to be in the optic canal that the probabilities point strongly to this location as the site of the lesion in most cases of obscure atrophy of the nerve after blows upon the skull. Vance⁵ in a report of 512 autopsies showed that a fracture of the anterior clinoid process accounted for a large proportion of the cases of optic nerve atrophy. Lillie and Adson³ reported two cases of callus formation in the canal following fracture which could not be demonstrated by x-ray at the time of accident.

Perhaps a considerable portion of the so-called congenital cases of optic atrophy occur from fractures of the skull in difficult births.

Injuries in the canal lead after two or three

months to descending atrophy. It behooves the examiner not to give an opinion on the basis of a normal fundus until sufficient time has elapsed for the possible appearance of atrophy.

The optic nerve in the orbit consists of a central part free from vessels and a distant part carrying them. Injuries occur in the central part three to four times as often as in the distal portion, due to the fact that injuries from weapons such as knives, et cetera, are likely to slide along the walls to the apex, and also it is there that the splinters of bone are most likely to cut the nerve.

Ophthalmic examination shows practically no change in the fundus at first, where the injury to the nerve is behind the entrance of the retinal vessels in the optic nerve, but in two to six weeks optic atrophy becomes apparent. Where the injury to the nerve is to the distal portion carrying the central retinal vessels, there will be a picture of embolism with marked edema of the disc, while the periphery may be normal.

The clinical picture is different where there is no interruption of continuity of the nerve, but where compression from a bony fragment or from hemorrhage has occurred. The course and results of these cases with hemorrhage are much more favorable than those due to the direct injuries to the nerve, for if the hemorrhage ceases before the nerve is fully compressed the ischemia which is at first present passes into venous stasis with edema, hemorrhage and neuroretinitis follows, the loss of vision is not complete and the patient may recover useful vision but with some amblyopia remaining. The peripheral fibers being most compressed in hemorrhage, there follows a contraction of the peripheral fields and the central vision may or may not remain normal. Varying field changes may be found depending upon the pressure upon the optic nerves.

There is a large proportion of cases of blindness which on autopsy are unexplained either by fracture through foramen compression or hemorrhage into the sheath. Laceration of the nerve, concussion or stretching has been thought to be a factor.

Nystagmus is fairly uncommon—when present is usually associated with lesions of the posterior fossa.

According to Curtin² pupillary changes are one of the most consistent and important signs and the presence of a unilateral dilated pupil is

usually found on the side of the involvement. It is thought by the neurosurgeons to be one of the most useful localizing signs. When the pupils are widely dilated bilaterally immediately after an accident, it is a very grave sign as a fatal outcome has followed in a great majority of these cases. Occasionally, one sees a ruptured sphincter caused by a direct blow to the eye and resulting in a permanently dilated pupil. This, however, is not as significant as other causes.

The difficulty oftentimes in making an accurate examination of the fundus without dilated pupils gives us incomplete data, but in this connection it is advisable to caution against the use of morphine or any mydriatics, lest the presence of pupillary changes be obscured.

Paralysis of the sixth nerve is fairly common; however, this is not true of the other cranial nerves. Due to the anatomical position of the abducens as it bends over the sharp apex of the petrous portion of the temporal bone and its longer course, it may be affected in almost any type of cerebral lesion and consequently has no localizing value.

The seventh nerve is frequently involved in basal fractures and often results in paralysis of the orbicularis. Involvement of the third nerve is not common; however, when the intrinsic portion is involved with loss of accommodation and pupillary reaction the prognosis is more serious. The fourth nerve or trochlear nerve is the least commonly affected. However, a fracture of the bony wall at the site of the pulley might result in paralysis of action of this muscle. One such case has been seen where a man was kicked by a horse.

Due to the fact that the internal carotid artery lies in the outer wall of the cavernous sinus, its injury often leads to an arteriovenous aneurysm.

The clinical picture is easily recognized. There is a unilateral proptosis of the globe with a synchronous pulsation of the globe and vessels with the heart beat. A thrill can be felt and a loud murmur heard over a wide area. This murmur is usually very annoying to the patient and may be the first symptom noted. There is always an edema of the lids and the conjunctiva, a stasis of all the vessels and usually some degree of papilledema. The movement of the globe is limited and there is usually a diplopia present, due to involvement of the sixth nerve.

These patients are all candidates for a surgical

ligation of the carotid artery, which is practically always successful.

THE ACCUMULATED EXPERIENCE OF THE DEPARTMENT OF PATHOLOGY, UNIVERSITY OF MINNESOTA, ON NEUROPSYCHIATRIC MATERIAL

I. General Review

A. B. BAKER, M.D., and H. H. NORAN, M.D.

Minneapolis, Minnesota

THE Department of Pathology at the University of Minnesota has, during the past three decades, performed an extremely large number of autopsies. Recently, we have had the opportunity and the facilities to undertake an analysis of all cases with nervous system involvement autopsied between the years 1919 through 1938. It seems that such a study might be of value in demonstrating the relative frequency of certain neurologic lesions when considered not in a specialized series such as occurs in neurologic institutes, but when observed in a very general unselected group of cases. The magnitude of this undertaking is demonstrated by the fact that the present study necessitated a careful review of 31,615 autopsy records and pathologic reports. Of these, 13,479 had recorded studies of the nervous system and were, therefore, carefully abstracted. The final selection of cases for the present study is shown in Table I.

TABLE I.

1. Total number of autopsies (1919-1938).....	31,615
2. Total number of brain or cord autopsies.....	13,337
3. Stillbirths and newborns (not included in study)	2,990
4. Cases in which brain studies were done only as a routine but no lesions observed.....	3,392
5. Cases included in present survey.....	6,985

It must be realized that extensive pathologic studies of the nervous system were not performed in every case. No attempt was made to recheck the actual material since such a process would have been mechanically impossible not only be-

cause of its magnitude but also because of the absence of much of the older material. Since all autopsies were performed by members of the Department of Pathology, one can reasonably assume that the pathologic observations were accurate. Many of the reports, however, were too brief to allow for an accurate classification and were, therefore, omitted from this review. The present paper is the first of a series and is intended to give a general survey of our material. In later studies, more detailed analysis of the individual groups of diseases will be attempted.

The various types of involvements of the nervous system can be roughly divided into thirteen large groups (Table II). Such a division

TABLE II. CLASSIFICATION OF NEUROPSYCHIATRIC MATERIAL

I Intracranial Tumors	520
II Diseases of Intracranial Vessels (arteriosclerosis, hemorrhage, softening, emboli, atrophy)	2,145
III Brain Trauma	2,033

X Nerve Lesions	4
XI Functional Mental Disturbances.....	93
XII Cerebral Malformations and Hydrocephalus	143
XIII Miscellaneous Group (idiocy, cretinism, mongolism, Little's disease)	21
(102 cases duplicated in more than one group)	

From the Division of Nervous and Mental Diseases and the Department of Pathology, University of Minnesota. Assistance in the accumulation of these data was furnished by the personnel of the Work Projects Administration, Official Number 165-1-71-124. Sub-Project Number 288.

is naturally quite arbitrary. We have followed the general arrangement used by one of us (A. B. B.) in a previous publication (Outline of Neuropathology).¹ A brief statement concerning each of these groups of lesions can now appropriately be undertaken.

Intracranial Tumors.—A separate study of these neoplasms has already been published.² This group was composed of 520 cases. In 487 the tumors were reexamined histologically and reclassified according to the newer terminology. A more detailed division of these tumors is given in Table III.

TABLE III. INTRACRANIAL NEOPLASMS

I Tumors of Nerves	5
II Tumors of Meninges.....	76
III Gliomas	242
IV Vascular Tumors	21
V Tumors of Mixed Tissue.....	2
VI Hypophyseal Tumors	20
VII Granulomas	30
VIII Metastatic	81
IX Miscellaneous	43

Diseases of Intracranial Vessels.—This was naturally one of the largest groups of lesions since it included such conditions as atherosclerosis, hemorrhage, encephalomalacia, embolus, as well as some clinically related processes such as hypoglycemia, cerebral atrophy, diabetic coma and uremia (Table IV).

TABLE IV. DISEASES OF INTRACRANIAL VESSELS

Cerebral atherosclerosis (severe).....	252
Cerebral hemorrhage	681
Cerebral softening	825
Cerebral emboli	201
Clinically related processes.....	59
Uremia	30
Diabetic coma	16
Hypoglycemia	13
Cerebral atrophy	27
Senile atrophy	25
Presenile atrophy	2
Subarachnoid hemorrhage	228
Subdural bleeding	47

Only those cases of cerebral atherosclerosis were included in which the involvement of the vessels was severe, even though no associated parenchymal lesions were observed. The most common etiologic factor in both the cerebral hemorrhages and softenings was a hypertension, causing 49 per cent of the hemorrhages and 33 per

cent of the softenings. Arteriosclerosis without hypertension was the next most common etiologic factor. By far the greatest number of hemorrhages were of the massive type, such lesions comprising 79 per cent of the total bleedings. Among the softenings, the multiple lesions and the large single foci occurred with equal frequency. It is probable that had more detailed pathologic studies been made, many more cases of multiple lesions would have been found.

There were 201 cases of cerebral emboli. The greatest number were infectious secondary to a subacute bacterial endocarditis. Only twelve were fat emboli and two were air emboli.

The "clinically related processes" included under this grouping were placed here primarily for convenience. A detailed discussion of the hypoglycemic cases has already been published.^{3,4} Although in neither diabetic coma nor in uremia have any constant specific cerebral alterations been observed, still the clinical picture certainly suggests a definite cerebral impairment. This may be physiologic or it may be structural with the changes so subtle that they cannot be picked up with our present techniques. However, since the symptoms appear clinically to be cerebral, these two conditions warrant inclusion in this study.

A more detailed analysis of this vascular group will form the basis of a future publication.

Brain Trauma.—Brain trauma comprised an unusually large number of cases. This is the result of a large coroner's service in which many of the deaths are traumatic. All cases of cerebral hemorrhage secondary to trauma were included with the traumatic series rather than with the vascular group.

Meningitis.—There were 743 cases of leptomeningitis and forty-nine cases of pachymeningitis. The former were divided into the purulent types (meningococcic, streptococcic, pneumococcic, staphylococcic, influenzal, colon bacillus) and the nonpurulent type (tuberculous, luetic, whooping cough).

All forms of purulent meningitis tend to be very similar histopathologically, making it imperative that bacteriologic studies be done in order to identify the causative organism. Since many of the patients were not hospitalized and therefore did not receive such bacteriologic studies, a large number remained unidentified and were classified merely as purulent meningitis. In

only 265 or 52 per cent of the 507 cases of purulent meningitis was the causative organism determined. Of these the streptococcus was the most common, followed by the pneumococcic and the meningococcic types. There were 236 cases of nonpurulent meningitis, of which 201 were of the tuberculous type.

The cases of pachymeningitis were comprised of twenty-seven cases of the nonsuppurative type and twenty-two cases of extradural and subdural abscesses.

Encephalitis.—The encephalitides were divided into the suppurative and the nonsuppurative types (Table V). There were 278 cases of the former, of which 157 were brain abscesses, 119 were sinus thromboses, and two were actinomycotic infections.

TABLE V. ENCEPHALITIS

1. Suppurative Encephalitis	278
a. Brain abscess	157
b. Sinus thrombosis	119
c. Actinomycotic infections	2
2. Nonsuppurative Encephalitis	504
a. Primary type	50
(1) Epidemic encephalitis	23
(2) Hemorrhagic encephalitis ..	27
(3) Rabies	0
b. Secondary type (following infectious diseases)	34
3. Encephalitis from soluble toxins (botulin, tetanus, diphtheria)	18
4. Toxic Encephalitis (heavy metals, poisons, drugs)	266
5. Parasitic Encephalitis	3
6. Miscellaneous	133

The nonsuppurative cases were divided into the primary types (epidemic encephalitis, hemorrhagic encephalitis, rabies) and the secondary types following infectious diseases, soluble toxins (botulinus, tetanus, diphtheria), poisoning with heavy metals and drugs (opium, barbiturates, alcohol, arsenic, lead, carbon monoxide, strychnine, cyanide, et cetera), parasitic invasion (torula, trichina, cysticercus), and a miscellaneous group. In the latter were included the cerebral complications following such conditions as heat stroke, sunstroke, anesthetic deaths, strangulation, suffocation, and electrocution.

In the secondary forms of encephalitis it was frequently difficult to determine whether the actual cause of the clinical symptoms was due to cerebral damage. Whenever a doubt existed, the

cases were excluded. Here also, because of the large coroner's service, the number of deaths from heavy metals, poisons and drugs were somewhat out of proportion to the other types of encephalitis.

The question might be raised as to the justification of calling many of the above forms of cerebral complication a true encephalitis. From a strictly neuropathologic point of view, this term should include only the inflammatory diseases of the brain, but actually it has come to be used for any cellular reaction, be it inflammatory or degenerative. This has resulted, no doubt, from the fact that changes listed as degenerative and those called inflammatory are in many cases histologically qualitatively the same. It is for this reason that under the clinical term of encephalitis one frequently includes not only those primary infectious processes but also those cerebral reactions secondary to infectious diseases, to drugs, and to heavy metals as well as to parasitic invasions. A discussion of this problem has already been published.⁵

Extrapyramidal Motor System Diseases.—This was a very small group composed of twenty-four cases of parkinsonism, two cases of Huntington's chorea and one of Sydenham's chorea. In extrapyramidal system diseases the course in the patient is often a long and chronic one with the patient usually drifting away from the original source of observation. For this reason there has been a great scarcity of post-mortem tissues available for study, and even when autopsies were obtained, the chief interest was centered upon the acute cause of death and the long-standing extrapyramidal system involvement was entirely overlooked. Most cases of Huntington's chorea become institutionalized and, therefore, are not observed in a routine autopsy service outside the state hospitals.

Demyelinating-sclerosing Diseases.—This most interesting group includes such conditions as Wilson's disease, multiple sclerosis, amyotrophic lateral sclerosis, subacute combined degeneration, Schilder's diffuse sclerosis, et cetera. These diseases are probably more common than our figures disclose, but similar to the extrapyramidal system involvements, they are chronic in course and, therefore, not seen frequently at autopsy. The advent of liver therapy has almost com-

pletely obliterated the deaths from combined sclerosis.

Spinal Cord.—The analysis of the lesions of the spinal cord was probably the most unsatisfactory of the entire series, primarily because a routine examination of the cord is not performed at most autopsies. Most of our cases were, therefore, highly selective. We have no accurate information concerning such common conditions as the vascular diseases of the cord. The majority of the cord cases were comprised of tumors, poliomyelitis, and the muscular dystrophies and atrophies where special interest was centered on the cord lesion.

Neurosyphilis.—There were 168 cases in this group divided as follows: eight, taboparesis; fourteen, tabes; twenty-six, paresis; two, gumma, twenty-two, meningovascular; and two, congenital. Of these cases, sixty-nine produced definite vascular damage and were also included under cerebral hemorrhage and softening.

Nerve Lesions.—Very few of these cases were available for study. Involvement of the peripheral nervous system is not infrequent clinically but apparently death from such lesions is uncommon.

Psychoses.—Naturally, in the general population autopsies on the functional mental states are infrequent because the obviously disturbed patient is frequently placed in a state hospital. Moreover, there is a great tendency on the part of the public to be secretive about such cases within their own families and for this reason the noninstitutionalized psychoses do not receive continuous medical supervision and rarely come to autopsy. However, sufficient clinical studies are available to show fairly accurately the relative frequency of these psychogenic disturbances within the general population.⁶

Nervous System Anomalies and Hydrocephalus.—Since newbirths and stillbirths were excluded from this study, many types of cerebral malformations, especially those producing death of the fetus, are lacking in our survey. The most frequent anomalies in this study were spinal bifida, internal hydrocephalus, encephalocele and porencephaly. Hydrocephalus with spina bifida comprised 41 per cent of all anomalies.

There were 120 cases of severe hydrocephalus. Of these, fifty were secondary while seventy were listed as primary. By far the most common cause of the secondary hydrocephalus was a chronic meningitis.

Miscellaneous Group.—In this group were included some widely scattered conditions such as feeble-mindedness, amaurotic idiocy, cretinism, mongolism, Little's disease, et cetera. The number of cases of each were very few and warrant no specific remarks.

Summary

1. A statistical study is present of all autopsies on the nervous system performed by the Department of Pathology, University of Minnesota, over the twenty-year period extending from 1919 through 1938.

2. The present study is the first in a series covering this material and is intended to give only a general survey. Detailed analyses of the individual groups of lesions will follow in later reports.

Even in the most disastrous wars it is clear that the casualties are trivial in comparison with the annual morbidity and mortality from wholly preventable causes suffered by the population. Along with the expenditure of dizzy billions to combat foreign foes, it would seem the part of wisdom to devote a respectable amount of our defense energies and resources to the conquest of the ever present and very real foes within our domestic circle, if for no other reason than the fact that the first line of military defense is the health of the civilian population.—K. INTRAPLEURAL PNEUMONOLYSIS

Experiences with This Procedure at Nopeming Sanatorium

G. A. HEDBERG, M.D.

Nopeming Sanatorium, Nopeming, Minnesota

IN the treatment of pulmonary tuberculosis the value of successful pneumothorax has been established beyond dispute. The frequency with which adhesion of the visceral and parietal pleura prevents such successful collapse has been discouragingly high. When the cavity has been held open by extensive fusion of the visceral and parietal pleura in the apex, as often happens in the fibroid type of case, thoracoplasty has been the best alternative. This procedure, however, is limited to the stabilized lesion with a good contralateral lung. In the more virulent types of tuberculosis, such as the exudative lesion, where pneumothorax is the ideal therapeutic measure, successful collapse is often prevented by adhesions of the string, cord, band, and sheet types. In the past, most of these pneumothoraces have had to be abandoned as failures. Sometimes the addition of phrenic nerve interruption has relaxed these adhesions enough to allow closure of the cavity. Attempts at stretching the adhesions by maintaining increased pressures were most often accompanied by serious complications, such as effusion and empyema, resulting from partial tearing of the interfering adhesions.

The procedure of intrapleural pneumonolysis affords a most satisfactory method of converting the incomplete and unsuccessful pneumothoraces into successful ones. At Nopeming Sanatorium our interest in this procedure dates back to 1933 when a patient was admitted to our sanatorium after having had her adhesions cut. During the next four years a number of cases with pneumothoraces with adhesions preventing closure of cavity were operated upon in the Duluth hospitals. Since August of 1938 the procedure of intrapleural pneumonolysis has been performed at Nopeming Sanatorium by the author. The experiences with the procedure of intrapleural pneumonolysis in this latter series of cases is the basis of this paper.

No attempt will be made to describe the operative procedure in detail. Briefly, two cannulae are inserted through intercostal spaces into the pleural cavity at points selected with regard to the

location of the adhesions. Through one an electrocautery is inserted and through the other a thoracoscope is passed so that adhesions may be cut under visual control. The operation itself is accompanied by little or no shock and is performed under local infiltration anesthesia. The method of cauterization used, I believe, is a matter of choice of the operator. We have used actual cautery in preference to electrodesiccation as we have found that we have been able to completely anesthetize the parietal attachment of the adhesions without difficulty by using this method.

In the earlier operations we attempted to cut string, cord, and band type adhesions which were relatively long and could be cut at some distance from their parietal attachment with safety. Later, we found that by injecting the adhesions at their parietal attachment that we could literally peel the attachment away from the chest wall safely and painlessly. By this method plus the use of a transilluminating light trabeculated sheet adhesions and relatively thick fleshy adhesions could be safely detached without serious complications. We have almost routinely inserted our cautery through a light carrier using the light for transillumination and better visualization at the site of the cauterization. Following the completion of the lysis, the intrapleural pressures are adjusted well on the negative side before the wound is closed. We have found that this has reduced emphysema to an unimportant factor. We seldom have noticeable emphysema in our cases except accompanying postoperative nausea or in the dyspneic patient. We have reduced postoperative nausea greatly by eliminating morphine from the preoperative medication.

For the first few days following operation the control of the collapsed lung must be based upon fluoroscopic examination. Due to the fact that the pneumothorax has been exposed to atmospheric pressure during the procedure a marked collapse of the lung with more or less atelectasis usually occurs. As a result, attempt to control the pneumothorax by intrapleural pressures alone would be highly misleading. Even after having left the intrapleural pressures relatively high on

the negative side, fluoroscopic examination the next morning often reveals the lung completely collapsed and the mediastinum shifted toward the contralateral side. The intrapleural pressures at

ered as early as possible as prolonged delay may result in marked thickening of the adhesions or in their partial tearing with subsequent effusion and infection of the pleural space. We feel that

Fig. 1. Extensive pathologic lesions throughout upper lobe with large apical cavity held open by multiple adhesions of all types mainly attached in dome of apex along line of subclavian vessels. Cavity closure and sputum conversion followed intrapleural pneumonolysis.

this time will produce higher negative readings than those found immediately following the operation. In spite of this, enough air should be removed to partially reexpand the collapsed lung. Failure to do this prolongs the atelectasis and usually produces a pleural effusion. More important than this, prolonged atelectasis may interfere with the drainage of the cavity and prevent rapid closure. We have found that it is usually necessary to remove 500 or 600 c.c. of air the day following the pneumonolysis in order to sufficiently aerate the uninvolved portion of the lung and to start it functioning with respiration. When this occurs, the intrapleural pressures again return to those of a normal pneumothorax. If at the time of the first fluoroscopic examination more than a trace of fluid is noted, an intrapleural hemorrhage must be suspected, especially if the temperature of the patient has been elevated. When this is encountered, aspiration with subsequent irrigation with saline solution should be done immediately.

Much has been written as to the optimum time following the initial pneumothorax to perform the operation of intrapleural pneumonolysis. We believe that interfering adhesions should be sev-

the optimum time is usually from four to six weeks following the initial pneumothorax as this time is sufficient to allow the patient to accommodate himself to the collapse. During this period no attempt is made to force the adhesions by increasing the intrapleural pressures. We have often found it wise to complete the procedure in two stages, cutting part of the adhesions at the first operation and then allowing the more fleshy type of adhesions to stretch somewhat before attempting to sever them. In these cases we have usually waited four to five weeks before we have reoperated. When pleural effusion is present it is best to allow the inflammatory reaction to subside. The type of adhesion cut and the extent of the pneumonolysis is governed somewhat by the knowledge of the lung disease present. Where the underlying cavity is widely patent, we have severed thick, fleshy, sheet type adhesions often attached in the region of the subclavian vessels which we would not have touched if no visual evidence of cavity remained. The risk involved in attempting to sever the various types of adhesions encountered must be evaluated and balanced against the risk of the uncontrolled underlying disease process.

As our confidence in this procedure has increased, we have broadened our indications for its use until at the present time we feel that the procedure of intrapleural pneumonolysis should be considered in every case in which pneumothorax has been attempted and the collapse of the lung is inadequate because of adhesions. By means of a successful pneumonolysis, we can maintain the most efficient type of selective collapse.

In any evaluation of the procedure it must be recognized that intrapleural pneumonolysis is not an independent measure of collapse therapy but an adjunct to pneumothorax. The results, therefore, are dependent not only on the operation but upon the subsequent management of the pneumothorax. It has been particularly popular with us because the majority of our pneumothoraces are maintained by our own medical staff even after the patient's discharge from the sanatorium. It is obvious that the procedure would be less attractive with those who must relinquish their control of the collapse once the patient has left the sanatorium.

In the analysis of our series of intrapleural pneumonolyses performed at Nopeming, an attempt is being made to present the type of case chosen and the condition of the collapsed lung, as well as that of the contralateral lung. The complications which we have encountered will be enumerated with a discussion of the importance of each. The present status of patients in whom the operation was performed previous to May, 1940, will be reviewed. The results of operation will be shown.

TABLE I. SERIES OPERATED AT NOPEMING
SANATORIUM

August, 1938, to August, 1940	
Pneumonolysis performed in one stage.....	61
Pneumonolysis performed in two stages.....	11
Total.....	72*
Exploratory Thorascopies.....	6

*Four patients had bilateral pneumonolysis.

In a total of seventy-eight attempts at intrapleural pneumonolysis the procedure was carried out in seventy-two instances. Eleven of these operations were done in two stages and in four patients bilateral pneumonolyses were performed. If at the time of operation, exploration reveals that the main adhesions preventing collapse were not severable, no attempt is made to cut inconse-

quential string or band type adhesions. Good judgment will dictate against subjecting the patient to possible complications of intrapleural pneumonolysis even though they be relatively benign, if it is obvious at the time of the exploration that the main adhesion cannot be safely cut.

The group of patients subjected to operation consisted of forty women and twenty-eight men. The age range in the women was fourteen to thirty-five years and in the men fourteen to fifty-nine.

TABLE II. STATUS OF PATIENTS

Women (aged 14 to 35).....	40
Men (aged 14 to 59).....	28
Total	68
<i>Diagnosis</i>	
Minimal	3
Moderate Advanced.....	25
Far Advanced	40
Total	68

However, only four patients in the entire series were over thirty-five years of age. As to their diagnosis, at the time of operation only three out of sixty-eight were minimal, the majority being far advanced.

To further analyze the condition of the patients operated upon in this series the next two tables show the status of the collapsed lung and of the contralateral lung respectively.

TABLE III. STATUS OF COLLAPSED LUNG

Interference with collapse.....	24*
Interference with collapse and positive sputum....	12
Patent cavity but negative sputum.....	9
Patent cavity and positive sputum.....	27
Total	72

*Nineteen had positive sputum, patent cavity or both previous to collapse.

The indications for intrapleural pneumonolysis as we have used them consist of:

1. Interference with collapse of diseased lung only.
2. Persistent positive sputum without cavity.
3. Patent cavity with negative sputum.
4. Patent cavity and positive sputum.

Lest one derive the impression that the first indication alone has been used too often in this series, it is to be noted that in this group of twenty-four cases nineteen had positive sputum,

patent cavity or both, previous to the pneumothorax. As the operation in the majority of these cases is performed within six weeks to two months following the initial pneumothorax, the search for tubercle bacilli was limited to that of examination of direct smear of sputum in the earlier cases or to the search of slides prepared from twenty-four-hour concentrates. Had the interval between the initial pneumothorax and the intrapleural pneumonolysis been more prolonged, I believe that many of this group would have fallen into one of the next three classifications. As previously stated, we have come to feel that our indications for this procedure are much wider as we have realized that the serious complications could be held to a very minimum. At the present time we have no hesitancy in advising intrapleural pneumonolysis even in cases of progressive minimal tuberculosis, not responding to bed rest even though tubercle bacilli have not been demonstrated by study of gastric contents and inoculation into guinea pig. We feel that if pneumothorax is indicated, any adhesions interfering with its most efficient collapse should be severed if thoracoscopic examination reveals that they are the type which may be cut without too great a risk.

TABLE IV. STATUS OF CONTRALATERAL LUNG

Negative	19
Minimal inactive.....	11
Minimal active.....	13
Moderately advanced.....	12
Moderately advanced collapsed by pneumothorax....	9
Far advanced.....	5
Far advanced collapsed by pneumothorax.....	2
Far advanced collapsed by oleothorax.....	1
Total	72

The extent of the disease and the type of lesion present in the contralateral lung is shown in Table IV. It will be noted that in forty-two of the seventy-two patients operated upon the contralateral lesion was extensive, active, or both. In this group of forty-two cases cavities were present in the contralateral lung in nine. Pneumothorax was present in eleven cases, one of which consisted of a complete collapse complicated by chronic tuberculous empyema. In one case the contralateral lung was collapsed by oleothorax. It will be seen that even though the operation of intrapleural pneumonolysis is successful and the pneumothorax is properly maintained,

that the status of the patient following operation is not necessarily an indication of the success of the operation as in many cases the extent of the lesions in the contralateral lung in itself could prevent clinical recovery of the patient from his pulmonary tuberculosis. In a large portion of this series, converting an unsuccessful pneumothorax due to adhesions to a successful one by intrapleural pneumonolysis was the only procedure which we could safely attempt as the status of the contralateral lung would have prevented control of the pathology by thoracoplasty.

TABLE V. POSTOPERATIVE COMPLICATIONS

Reëxpansion of lung.....	1
Hemoptysis	2
Hemothorax	4
Transient effusion and hematoma.....	1
Transient effusion.....	14
Persistent effusion requiring aspiration.....	4
Tuberculous empyema.....	2

The frequency of postoperative complications encountered in our series is listed in the above table. Emphysema has not been included in this list of complications. We have seldom encountered it in our series farther than two inches from the cannula wounds. In five instances it was of moderate extent. In one case it was very extensive, resulting in the temporary reëxpansion of the lung and partial reattachment of the adhesion. However, pneumothorax was reëstablished without difficulty and the adhesion detached itself two weeks after surgery. Hemoptysis occurred in two cases. The presence of blood in the pleural space was recognized in four cases with subsequent aspiration. In one case a perforating branch of an intercostal artery was severed and retracted behind the parietal pleura resulting in a hematoma which was noticeable in fluoroscopic examination and x-ray for three weeks following the surgical procedure. In this case a mild transient effusion was also encountered. Fourteen cases had transient effusion. By this, I mean small amounts of fluid noticed at the times of subsequent fluoroscopic examinations which disappeared spontaneously within 3 weeks from the operation. In four, effusions were more persistent and required aspiration before their complete disappearance was noted. Tuberculous empyema was encountered in two cases. In both of these an attempt had been made to sever an adhesion which was subsequently found to be uncuttable after a portion of it had been cauterized. In one case the

empyema was cured by simple aspiration and in the other, where the lysis was unsuccessful in closing the cavity, a thoracoplasty was performed. We have encountered no cases of mixed empyema in our series and we have had no deaths which could be attributed to the surgical procedure.

TABLE VI. STATUS OF PATIENTS OPERATED SIX MONTHS OR OVER

Discharged	35
Medically approved for discharge.....	2
Subsequent thoracoplasty done.....	1
Still under sanatorium treatment.....	14
Dead from extension of disease.....	2
—	—
Total	54

The status of patients more than six months after operation is presented because of our interest in what has happened to them. It is not a true measure of the success of the procedure of intrapleural pneumonolysis. The subsequent course of the patient is determined not only by the state of the collapsed lung but by the condition of the contralateral lung and any extrapulmonary involvement. The average interval between the time of operation and discharge from the sanatorium in the first group of thirty-five is eight and one-half months. Of those not included in this series of fifty-four patients, an additional five have been discharged from the sanatorium. Of the two patients dead from extension of the disease, one had extensive bilateral disease with bilateral cavitation. Pneumothorax had been abandoned on the contralateral side and a partial pneumonolysis of the collapsed lung failed to close the cavity. In the other case, also with an extensive bilateral involvement with bilateral cavitation, cavity was closed following the pneu-

monolysis on the left side but the disease process in the contralateral lung was uncontrollable and the patient died from this involvement plus tuberculous enterocolitis.

TABLE VII. RESULT OF SURGERY

Satisfactory collapse.....	67
Pneumonolysis incomplete and unsuccessful.....	3
Pneumonolysis complete but cavity patent.....	2
—	—
Total	72

The final table shows the results of surgery. In the seventy-two cases in which intrapleural pneumonolysis was done a satisfactory collapse was obtained in sixty-seven. The pneumonolysis was incomplete and unsuccessful in three. All adhesions were cut with an apparent adequate pneumothorax but the cavity has failed to close in two cases up to the present time.

Conclusion

Our experience with the procedure of intrapleural pneumonolysis at Nopeming Sanatorium leads us to believe that it is a most satisfactory method of converting an unsuccessful pneumothorax into a successful one. During the two years, from August, 1938, to August, 1940, we have performed this procedure at the sanatorium and have had an opportunity to thoroughly study the procedure from the standpoint of complications and results. We believe that the procedure in competent hands is highly successful and that there are very few serious complications. We believe that all cases of pneumothorax in which adhesions interfere with collapse of diseased lung should be considered for the procedure of pneumonolysis in order to effect the most efficient results.

Tuberculosis occupies one of the first places in the disorganization of family life, both socially and economically. It breaks up homes, separates families, destroys husband-wife and parent-child relationships; and it renders many of its victims incapable of resuming their places in society. Economically, the cost of this disease to the community is tremendous. It costs a community from \$2,000 to \$5,000 to care for each case of diagnosed tuberculosis, depending upon the stage of advancement. It has its highest incidence during the most productive years of life, and the financial loss to the patient and to the country as a whole amounts to millions of dollars annually. From an epidemiological standpoint, the disease has the greatest incidence of any disease, with the possible exception of gonorrhea and syphilis.—GRACE M. LONGHURST, R.N., *Amer. Jour. of Nursing*, Jan., 1942.

DIFFERENTIAL DIAGNOSIS OF IDIOPATHIC LOW BACK PAIN

RALPH K. GHORMLEY, M.D.
Rochester, Minnesota

ANY attempt to simplify this subject is necessarily fraught with difficulties because of the many divergent opinions extant as to causes of backache, and because of many other factors of less import. It must be admitted, however, that those who have been interested in this subject and have followed its progress realize that during the past few years many facts have come to light which help greatly in analysis of these cases.

Proper differential diagnosis must include not only the most frequent conditions seen as causative factors in low back pain, but must recognize also that there are some types of backache which cannot properly be filed in any group. In some instances pain may be referable to lesions not situated in the spinal column, the spinal muscles, aponeuroses or in the nervous system. Above all, it must be recognized that not infrequently, if a patient can be reassured that he does not have cancer and that his kidneys are in good condition, backache will in many instances disappear.

In many types of backache some underlying lesion of major importance can be found. It has always been my feeling that the most important approach in any case of pain in the back must rule in or out any recognizable lesion which might cause the symptoms of which the patient complains. Such lesions may be of a very serious nature, from the standpoint of either ultimate

From the Section on Orthopedic Surgery, The Mayo Clinic, Rochester, Minnesota.

prognosis or actual pain and disability. A brief presentation of some lesions of importance which often underlie certain types of backache is given (Table I). This table is by no means complete, but at least it includes some of the more commonly encountered conditions which may be the basis or bases of the patient's complaint.

It must be borne in mind that low back pain may follow the onset of the actual lesion by months or years. For instance, spondylolisthesis may be present throughout a patient's childhood and adolescence, yet it may not produce symptoms until the patient has reached middle adult life or until after he has subjected his back to some unusual stress or strain. Congenital anomalies likewise may exist for years without producing symptoms. If a patient who has an anomaly or anomalies is subjected to injury or strain of more or less severity, symptoms may appear at once.

A severe, acute onset may be encountered in a case of myositis or myofascitis, pathologic fracture, or herniation of the nucleus pulposus. The physical observations common to any one of the aforementioned conditions may be identical to those of the other three at the time of onset. Roentgenograms will identify pathologic fracture, but in the other conditions mentioned, roentgenograms may not be of help. The patient's response to treatment often will help to bring diag-

TABLE I. LESIONS WHICH OFTEN UNDERLIE PAIN IN LOWER PART OF THE BACK

	Type of lesion present					
	Postural strain	Static or post-traumatic	Rheumatic	Infectious (other types)	Senescent	Neoplastic
Probable pathologic condition present	Increased lordosis Adolescent, other round back types Obesity Faulty body mechanics Faulty foot mechanics	Spondylolisthesis Defective pedicles Old fractures (Kümmells) Fractured facets Fractured pedicles Thin disks; other disk lesions Hypertrophic and post-traumatic changes Congenital anomalies	Infectious arthritis Spondylitis deformans Myositis	Tuberculosis Osteitis—benign—Paget's Intervertebral disks, inflammatory Brucella abortus Typhoid (spinal column)	Senile osteoporosis Senescent and hypertrophic arthritis	A. nostic factors into the open and to make formation of an accurate diagnosis possible.

What diagnostic points are most important in the process of the physician's arriving at a decision as to the type of backache he has been called on to treat? To me, one of the most important diagnostic points in such circumstances is the type of pain present. Table II briefly sets forth my impressions concerning this subject. It must be admitted that there may be variations from any set tabulation of symptoms and that in many instances more than one type of pain will be present, but for a working outline Table II is believed to be helpful.

Similarly, observation of a patient for days

or weeks or even months or years may be necessary before a correct diagnosis can be made. Progression of an osseous lesion almost invariably is likely to occur in cases of tuberculosis, spondylitis deformans and metastatic malignancy, as well as in many other active and neoplastic conditions (Fig. 1*a* and *b*), and in many cases it is on the physician's observation of such progression as well as on his noting of the response of the patient to treatment that the final diagnosis may depend.

It should be emphasized herein that such lesions may be overlooked if they are in an early stage, in spite of complete examination of the patient. It is my own impression, for instance, that in

its earliest stages spondylitis deformans is very easily overlooked, and that not until the clinical picture has been fairly well established can the diagnosis be made. The typical picture of spondylitis is that of a spinal column in which motion is almost wholly limited, a sharply limited chest expansion, and an elevated sedimentation rate. Augmenting such a picture, roentgenograms almost always show marked fuzziness with some sclerosis of the sacro-iliac margins.

After he has made an analysis of the type of pain present, the physician turns to the physical observations. Of these, muscle spasm, tender regions, and deformities are the most important. The physician must always be able to distinguish between true muscle spasm and the voluntary type of spasm which is often exhibited by the malingerer or neurotic person in search of compensation. Integrity of the whole diagnosis in such cases depends on the ability of the examiner to recognize this difference in muscle spasm. It can always be recognized by the experienced examiner. True muscle spasm is easily recognized by a hard, firm feeling on palpation of the muscle in question, and by a list or limitation of motion in whatever direction the muscle may be antagonistic. Tender points may be misleading, but if they are consistently present on repeated examination, they

are of the utmost significance in localization of a lesion or in demonstration of referred tenderness, such as may be encountered along the pathways of nerves at times.

The importance of making good roentgenograms and accurate interpretation of them by one experienced in reading roentgenograms cannot be overestimated. Many a lesion of prime importance may be overlooked in poorly prepared roentgenograms or by one inexperienced in interpretation of roentgenograms.

Finally, complete laboratory facilities may be necessary in the diagnosis of the condition under consideration. Such factors as the sedimentation rate, the test for Bence-Jones proteinuria, estimation of the content of phosphatase in the blood, expert interpretation of changes in blood smears, and many other tests may at times be most helpful and indeed necessary in the making of an accurate diagnosis.

In all obscure cases, observation of the patient at intervals for a period of months will serve to help in establishment of a definite diagnosis. Treatment, in the meantime, must be symptomatic and if possible the patient should be made to understand that his condition demands observation for such a period as the physician may think necessary.

QUINIDINE IN AURICULAR FIBRILLATION

R. BERMAN, M.D., and J. S. BLUMENTHAL, M.D.
Minneapolis, Minnesota

THE use of quinidine in attempting to restore normal cardiac rhythm in the presence of auricular fibrillation is still a moot question. A great deal of investigation has been carried on with this drug,^{2,6} which is an alkaloid of cinchona and isomeric with quinine.¹ It is readily absorbed in the upper portion of the gastro-intestinal tract, and it is eliminated chiefly by the kidneys. Weiss and Hatcher¹¹ and S. Weisman¹⁰ found quinidine almost entirely excreted in about four hours in animals. Quinidine delays intraventricular conduction time and the auriculoventricular interval. The refractory period has also been found lengthened by most investigators.^{3,4,5,7}

This report is a study of ninety-seven cases of auricular fibrillation seen during the calendar year of 1939 at the heart clinics of the University

of Minnesota and the Minneapolis General Hospital. Quinidine was given to alternate patients and the others constituted a control group. Forty-eight treated patients were administered quinidine in doses up to forty-eight grains a day. In the group which received quinidine were twelve valvular lesions, two hyperthyroid hearts, thirty-three hypertensives and coronary cases, and one fibrillation of unknown origin. Fifteen were regulated and thirty-three did not respond favorably to the drug. There were six fatalities in this group. The results closely parallel the report of Smith and Boland from the Mayo Clinic.⁸ The control group consisted of nineteen valvular cases, twenty-nine with hypertension or coronary sclerosis, and one auricular fibrillation of unknown etiology. None of this group became reg-

ular during the period of the study and two deaths occurred. In the treated group, after the heart rate was retarded with digitalis, quinidine was administered according to the method of Weisman.¹⁰ The total daily dose was divided into three or four equal parts which were administered at hourly intervals during the morning. The daily dose was increased by three or five grains as long as fibrillation persisted and until toxic symptoms developed. The highest dose given was forty-eight grains. Toxic symptoms of nausea, vomiting, diarrhea, collapse, and death occurred following doses as low as three grains.

Eight of the fifteen regulated patients remained regular when last seen, two to twenty-four months after regulation, after an average interval of fourteen months. Eleven relapsed into fibrillation or some other irregularity in one to fourteen months, remaining regular for an average of six months.

The six fatal cases are summarized below:

Case 1.—This patient was a man eighty years old, with mild hypertension of 154 systolic and 80 diastolic, and coronary disease. The heart was enlarged to the left with a total transverse diameter of 17.1 cm. in a 26 cm. chest. He was dyspneic but not markedly decompensated. The electrocardiogram shows auricular fibrillation, left preponderance and a flat T_1 . Fibrillation had been present about six months. After digitalization with moderate improvement, quinidine therapy was started with 3 grains. The patient died suddenly in the afternoon of the first day's use of quinidine. No autopsy was obtained.

Case 2.—This patient, a female, aged sixty, had hypertension of 164 systolic and 72 diastolic. The heart measured 16.8 cm. in diameter and the chest 31 cm. No marked decompensation was noted. The electrocardiogram showed a diphasic T_1 , left preponderance, and auricular fibrillation. Fibrillation had been present only two weeks. After digitalization, quinidine was started and increased gradually to 30 grains daily. She then developed a severe diarrhea, felt very sick and died suddenly. No autopsy could be obtained.

Case 3.—This man, aged sixty-seven, had coronary disease. His heart was not enlarged, being 11.2 cm. in diameter, with a chest diameter of 26.8 cm. The electrocardiogram showed a left preponderance, auricular fibrillation and a flat T_1T_2 . There was a history of cancer of the stomach with gastric resection three years previous. No signs of recurrence were noted on complete examination including gastro-intestinal x-ray and gastroscopy. After a known fibrillation of six months' duration, he was digitalized and quinidine started. The dose was gradually increased to 36 grains daily. The patient died suddenly. No autopsy was obtained.

Case 4.—This man, aged 71, had coronary disease. His heart was enlarged to the left with a transverse diameter of 16.5 cm. in a chest measuring 26 cm. The electrocardiogram showed auricular fibrillation and a *neg. T₁T₂*. His marked decompensation improved on digitalization. After known fibrillation of one year, quinidine therapy was started. His heart became regular on 30 grains daily. He was found dead on the day after his heart had become regular. Autopsy findings revealed a heart 500 grams in weight with no marked coronary changes. The right lung weighed 925 grams, the left 1050 with no consideration, but a frothy fluid was noted. Pathological findings were hypertensive heart disease, cardiac dilatation and hypertrophy, congestion of liver and spleen, pulmonary edema.

Case 5.—This man, aged 54, had a hypertensive heart with a blood pressure of 180 systolic and 110 diastolic. He gave a history of asthma of many years' duration. He had been fibrillating three years. His heart measured 21 cm. and chest 27.5 cm. in diameter. An electrocardiogram showed auricular fibrillation and left preponderance. He was greatly decompensated but improved on digitalization. Quinidine was started and increased to 15 grains daily when the patient died suddenly. Autopsy revealed a heart weighing 526 grams and no coronary changes. Pathological diagnoses were hypertensive heart disease and arteriosclerotic kidneys.

Case 6.—This patient was a seventy-three-year-old woman with hypertension of 200 to 240 systolic and 100-110 diastolic pressure. The heart was markedly enlarged to the left with a total transverse diameter of 17.3 cm. in a 30.3 cm. chest. The electrocardiogram showed the fibrillation and a negative T_1 and diphasic T_2 . After six years of known fibrillation, quinidine therapy was instituted and increased in nine days from 3 to 33 grains a day. The afternoon of the ninth day the visiting cardiac nurse reported that the heart rhythm was regular. That evening nausea, vomiting, and collapse occurred followed by bloody diarrhea, abdominal distention, and death. Autopsy was refused by the family. The probable immediate cause of death was a mesenteric embolus.

Summary

1. Ninety-seven cases of auricular fibrillation were studied. Of this group alternate cases were selected for treatment with quinidine.

2. Of the forty-eight treated patients, fifteen became regular for periods of from one month to twenty-four months. Seven of these relapsed into fibrillation or other arrhythmia after an average interval of six months.

3. Six deaths occurred in the treated group and two deaths in the control group.

Conclusions

Quinidine is a powerful and a dangerous drug when used to regulate auricular fibrillation. It

should not be used when the fibrillation has been established for years, when the patient is old and feeble, when the heart is extremely large or shows marked coronary disease, when compensation cannot be established, when the heart cannot be slowed with digitalis. Fatalities may occur with very small doses.

CASE REPORTS

COLON BACILLUS MENINGITIS

Report of Case in a Newborn with Recovery Following Sulfapyridine Therapy

CARL O. KOHLBRY, M.D.

Duluth, Minnesota

COLON bacillus meningitis, though rare, may occur at any age. It is, however, more commonly encountered during infancy, most especially in the newborn period or shortly thereafter. Treatment in the past has been almost universally without avail. A very thorough study of this disease and the literature pertaining thereto has just been made by Barrett, Rammelkamp, and Worcester.¹ These authors report two of their own cases as well as two other cases in the literature with recovery following sulfonamide therapy. Those interested are referred to this most excellent monograph.

Case Report

C. W., a baby girl, the first child of healthy parents, was born June 16, 1941. Her birth weight was 3,070 grams. Examination at birth by the attending physician showed the infant to be normal except for an abnormality of the right ear, the external auditory canal apparently being nonexistent and the auricle itself very rudimentary. Its first week of life, spent in the hospital newborn nursery, was uneventful.

On June 23, 1941, at the age of seven days, a rectal temperature of 101° was noted. Next day, June 24, her temperature rose to 102°, and the baby's cry became sharper and more piercing. The nursery supervisor also reported that her fontanel seemed full and tense.

I was first called to see this infant on June 24. Its general condition was good, the only abnormalities present being the temperature of 102°, a white blood count of 17,000, and a definite bulging of the fontanel.

Spinal puncture yielded 5 c.c. of very turbid, syrupy, greenish yellow fluid with a cell count of 3,300 p.m.n.'s and 3,000 lymphocytes to the cubic millimeter. The spinal fluid protein was 1,700 milligrams per cent and the sugar 9 milligrams per cent. Smears of this fluid

revealed gram negative rods; culture yielded similar organisms, later proven to be *Bacillus coli*.

Treatment with sulfapyridine was instituted at once both by mouth and subcutaneously, as noted hereafter. The infant's temperature continued between 101° and 103° for three days, i.e., through June 28, after which it dropped to normal and continued so throughout the remainder of the hospital stay. During the period of fever the baby occasionally exhibited mild tonic rigidity. Repeated daily spinal punctures showed the fluid becoming less cloudy; at the same time tension of the fontanel became gradually less. By June 29 the cell count had fallen to 240 per cubic millimeter and no organisms could be found on smear or culture. By July 1, six days after institution of therapy, the fluid was practically clear. One week later, July 8, it was clear with a cell count of 32. By July 14 the cell count had fallen to 5 per cubic millimeter.

Cyanosis appeared during the period of intensive chemotherapy, and later a mild secondary anemia became evident. Both findings were believed to be due to the sulfapyridine; they improved with no treatment other than discontinuance of the drug.

The infant was discharged from the hospital July 21, 1941, at the age of five weeks, weighing 3,430 grams, a gain of 340 grams over its birth weight. She was readmitted four days later because of a temperature which subsided within twenty-four hours and was of indeterminate origin. The spinal fluid was normal on this entrance. She was again discharged on August 1, one week after entrance.

Progress since this time has been uneventful. At present, at the age of four and a half months, she appears to be a normal child, weighing 6,525 grams, or 14½ pounds.

Laboratory.—The spinal fluids of June 24, 25, and 26 all yielded gram-negative rods on direct smear. These organisms were grown on culture from the fluids of June 24 and 25. Organisms were absent on

CASE REPORTS

direct smear and culture of the fluids of June 27 and thereafter.

Dr. J. J. Grabow, pathologist of St. Mary's Hospital, reported that the organism in the spinal fluid was a gram-negative rod. Inoculation of treptose broth resulted in an abundant growth of these rods. When subcultured on eosin methyl blue medium they produced the typical metallic sheen characteristic of *B. coli*.

Treatment.—Sulfapyridine was given this child orally from the time it was first seen on June 24. An original dose of 4 grains was given and thereafter 2 grains was administered every four hours both day and night, making a total of 12 grains daily for five days through June 28. The dosage was cut to 1 grain every four hours, or 6 grains daily, from this date through July 7; then 1 grain every six hours, or 4 grains daily, through July 8, on which date it was discontinued.

In addition the child was given 25 c.c. of 0.3 per cent sodium sulfapyridine subcutaneously on June 26; this

was repeated on June 27. Throughout the forty-eight hours of June 28 and 29 it was given 50 c.c. of a 0.5 per cent solution subcutaneously every eight hours for a total of six injections.

Blood and spinal fluid levels of sulfapyridine were unfortunately not obtained.

Summary

A case of *Colon bacillus meningitis* in the newborn with recovery following sulfapyridine therapy is reported. The treatment was comparatively simple, the response very rapid, and recovery is apparently complete without residue. Portal of entry of the infection was not identified.

PRESUMPTIVE TUBERCULOUS ENTERITIS

JOHN M. BERKMAN, M.D. and J. ARNOLD BARGEN, M.D.

Rochester, Minnesota

SYMPTOMS of intestinal disease in the case which we are reporting were mild and yet, because of the disease of the spinal column and the family history, a thorough investigation seemed indicated. The symptoms were strikingly similar to those commonly associated with the syndrome of the irritable bowel. Several unexplained attacks of abdominal distress had occurred, but otherwise the history was not impressive, although the patient emphasized that she had not felt as well as usual in the six months prior to registration at the Mayo Clinic. Common symptoms of enteritis, such as diarrhea, anemia, loss of weight, and so forth, which are characteristic of such conditions as nontropical sprue or nonspecific hypertrophic jejuno-ileitis, were absent, yet roentgenologic investigation of the small intestine in this case suggests the presence of extensive enteritis.

In the case of tuberculosis enteritis reported by Schapiro, both the clinical manifestations and the findings at roentgenologic investigations indicated a diagnosis of nonspecific hypertrophic jejuno-ileitis. Death occurred in this case and a definite diagnosis from examination of the small bowel alone could not be established at necropsy. Microscopic examination revealed marked hyperplastic and exudative inflammatory changes and occasional giant cells, but no definite formation of tubercles was found in the wall of the small bowel. However, anatomic tubercles were found in the enlarged regional lymph nodes. In many instances, tuberculosis of the bowel has been suspected; however, proof of the presence of such a condition has been lacking in most instances. Examination of stools for *Mycobacterium tuberculosis* is usually of no assistance and such proof as presented by Schapiro is unusual.

Inasmuch as the etiology must of necessity be pre-

sumptive, it seems advisable to review briefly the data on our patient and her family.

Report of Case

The family history was important. The patient was one of fourteen children. In 1919, the father had died of pulmonary tuberculosis. In 1935, one other member of the family, and possibly the patient had tuberculosis. Two sisters had been found to have pulmonary tuberculosis; they had died in a sanatorium. Because of these two occurrences of pulmonary tuberculosis, each remaining member of the family had been examined for its presence. In October, 1940, another sister who had not recovered completely from an infection of the respiratory tract and who had not been well for the subsequent nine months had been found to have pulmonary tuberculosis. She had entered a sanatorium and death had occurred two weeks subsequent to admission. Following this death, the remaining members of the family were re-examined. A daughter of the sister who had died in 1940 was found to have pulmonary tuberculosis and at the time of this writing is in a sanatorium. This brings the total number of deaths from pulmonary tuberculosis in this family to four.

In 1932 the patient had had an attack of abdominal pain, the details of which she had forgotten. The physician in her home locality had raised the question of intestinal obstruction; however, after a short time her symptoms had disappeared entirely. A year later, in 1933, she had experienced another attack of abdominal pain; a diagnosis of appendicitis had been made and appendectomy had been performed.

The patient, a woman seventeen years of age, registered at the Mayo Clinic on August 26, 1935. She had been examined by the physician in her home locality, who had found a tumorous mass at the level of the eighth thoracic vertebra. The patient related that she had been aware of this mass for six months. However, there had been no local symptoms and she had been in good health.

On examination at the clinic tenderness was absent over the tumorous mass and motion was not limited; however, some kyphosis was present at the level of the

From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota.

CASE REPORTS

eighth thoracic vertebra. The lymph nodes in both supraclavicular and left axillary regions were moderately enlarged and firm. A diagnosis of tuberculosis of

of an elevated temperature of 99.4° F. (37.4° C.) there were no other significant physical findings. Results of the laboratory tests were inconclusive and results of the

Fig. 1. Thoracic portion of the spinal column as it appeared at roentgenologic examination in August, 1935, revealing tuberculosis of the eighth and ninth thoracic vertebrae associated with paravertebral abscess.

Fig. 2. Old healed tuberculous lesions of vertebrae and also healed calcified cervical lymph nodes, July, 1935.

the eighth and ninth thoracic vertebrae associated with para-vertebral abscess was made (Fig. 1). At operation, bone was grafted to the seventh and eleventh thoracic vertebrae. Convalescence was uneventful. As the patient lived nearby, observations were made occasionally for several years after operation (Fig. 2). Two years after operation the patient obtained work as a housemaid and continued at this employment until enteritis developed in July, 1939.

On July 26, 1939, the patient, while stooping, experienced a cramping pain in the right upper quadrant of the abdomen, which she described as so severe that it had been difficult to breathe and that for the moment it had prevented her from talking. The entire episode had lasted only twenty minutes. She had noted tenderness in this region prior to the attack. At examination a short time following the attack of pain she had no complaints whatsoever. In the evening of the same day the pain recurred and again was severe. She could not recline because of the pain and was more comfortable in a sitting position. Tenderness was present in both lower quadrants and the upper right quadrant of the abdomen. This attack lasted approximately two hours and then the pain disappeared completely. After this episode, with the exception of not having felt as well as usual for the six months prior to July, 1939, when she again came to the clinic, she had not had any abdominal symptoms. Diarrhea, gaseous distention or other significant symptoms referable to the abdomen had been absent.

On July 27, 1939, she was examined at the clinic. Tenderness was present in both the upper and right lower quadrants of the abdomen. With the exception

routine blood studies were either normal or negative. Roentgenologic examination of the gall bladder, kidneys, ureters, bladder and colon disclosed nothing abnormal; however, the terminal portion of the ileum was not visualized. Roentgenologic studies of the small bowel revealed that granulomatous enteritis involved the lower portion of the jejunum and much of the ileum in a patchy distribution, which may have been a tuberculous process. Because of the extent of the apparent involvement of the bowel by this inflammation, surgical intervention seemed inadvisable. Also, because of the extent of involvement of the bowel, further attempts at better roentgenologic visualization of the terminal portion of the ileum were not indicated (Fig. 3).

The first urinalysis disclosed hematuria, grade 1, and pyuria, grade 2, with 50 cells in each microscopic field as viewed under the high power objective. A second urinalysis disclosed an occasional erythrocyte and pyuria, grade 2. A specimen of urine obtained by catheterization disclosed the presence of pyuria, grade 1. These gradings were made on a basis of 1 to 4. Excretory urograms failed to reveal disease of the urinary tract.

The patient was instructed to take a soft, low residue diet high in vitamins, to which cod liver oil, yeast and a tablespoonful (15 c.c.) of calcium lactate in hot water were added daily. Complete rest in bed was advised and she was dismissed on August 8, 1939.

The patient returned to the clinic on October 10, 1939. A record of the temperature taken each day at 4 p.m. revealed frequent rises to 99.4° F. and 99.6° F. (37.4° C. and 37.5° C.). She had felt well and had gained 4 pounds (1.8 kg.). Roentgenologic examination

of the small intestine at this time revealed nothing abnormal except for evidence of mural thickening in the 6 or 8 inches (15 or 20 cm.) of the terminal portion of

day or two, when it had been 99°F. (37.2°C.). At this visit careful roentgenologic studies of the small bowel again disclosed nothing abnormal.

Fig. 3. The small intestine as it appeared at the first roentgenologic examination in July, 1939. The changes manifested are those of diffuse jejuno-ileitis. In the lowermost portion of the ileum the hyperplastic element seemed to be more prominent.

Fig. 4. Mural thickening of the terminal portion of the ileum, October, 1939.

the ileum (Fig. 4). She was dismissed with instructions to continue the same regimen.

The patient was seen again on January 23, 1940, six months after the diagnosis of granulomatous enteritis had been made. Her temperature, taken at 4 p.m. each day, had been normal from October 21, 1939, to this time, with the exception of a week in which her temperature ranged from 98.8° F. to 99.2° F. (37.1° C. to 37.3° C.). Roentgenologic examination of the colon disclosed nothing abnormal; however, the terminal portion of the ileum again could not be visualized, but roentgenologic study of the small bowel disclosed nothing abnormal. She was dismissed with the same instructions as previously.

On April 30, 1940, the patient was seen and stated that her temperature had remained normal. She had remained in bed until March 15, 1940, and then had begun to walk about, at first for a short time but gradually remaining up for longer periods. At this visit she was feeling well and had no complaints; however, she had been resting most of each day.

The patient was last seen on October 26, 1940, fifteen months after the diagnosis of enteritis had been made. She was ambulatory all day but had been retiring early in the evening. She had been assisting in the household duties but still observing her periods of rest. Her temperature had been normal with the exception of a

Comment

This case brings up several common diseases for consideration and distinction. Instances of acute jejuno-ileitis are not seen by the roentgenologist because the attacks are not of sufficient duration and, as a general rule, the symptoms are too acute to warrant roentgenologic investigation. It seems reasonable that non-tropical sprue need not be considered in this case because of the lack of symptoms of the type associated with sprue. The absence of diarrhea and anemia are of interest. The roentgenologic findings, which were not those of sprue, disappeared in a comparatively short time, although no form of liver was used in the treatment.

Nonspecific hypertrophic jejuno-ileitis must be considered in the differential diagnosis. It must be admitted that the duration of the symptoms and the apparent good health of the patient are out of proportion to the roentgenologic findings. The patchy distribution of the inflammatory process is not characteristic of nonspecific hypertrophic jejuno-ileitis, although "skip areas" do occur in this condition. The disappear-

ance of roentgenologic findings in such a short period is not an accompaniment of nonspecific hypertrophic jejuno-ileitis. It must also be remembered that involvement of the small bowel was so extensive that surgical intervention was felt to be hopeless.

We feel that the family history and the patient's history of previous tuberculosis of the spinal column, in

spite of the absence of active pulmonary disease, make a presumptive diagnosis of tuberculous enteritis tenable. In other similar cases findings on surgical exploration offer precedent for such a diagnosis.

PRESENT ROLE OF "ALCOHOLICS ANONYMOUS" IN THE TREATMENT OF CHRONIC ALCOHOLISM

PHILIP H. HEERSEMA, M.D.
Rochester, Minnesota

IN THE September, 1941, issue of MINNESOTA MEDICINE, there appeared an editorial on "Alcoholics Anonymous," briefly describing the history, growth, objectives and mechanics of this seven-year-old organization. At the present time there are two chapters of this unique society operating in this state. These are situated in Minneapolis and Saint Paul. Each of these organizations, which have been in operation less than a year, have enjoyed consistent growth and have demonstrated achievement which warrants, even at this relatively early date, the consideration and respect of any physician who has attempted to treat chronic alcoholism. In general, the progressive development of the Minnesota groups is similar to the establishment and growth of the organizations in the fifty or more other cities which constitute this national movement.

In December, 1941, I had the opportunity of attending a general weekly meeting of the Minneapolis organization which was made up of approximately 125 members (about eighty of whom, approximately two-thirds, are expected to remain abstinent according to the experience of other cities). Also there were present the wives, or husbands, of many of the members; well-wishing although somewhat curious friends, and about a dozen equally curious members of the medical profession, including myself. This meeting was conducted in an efficient and highly commendable manner with an unusual spirit of coöperation. Most of all, one could appreciate the very purposeful direction—namely, that of the mutual objective of the members in defeating the habit of alcoholism. At this same meeting I had the opportunity of renewing the acquaintance and briefly discussing the present attitude of two former patients. The apparent, and what impressed me as real, improvement in the condition of these patients deserves a report and probable recognition of Alcoholics Anonymous as an important treatment and rehabilitation agency for patients who have chronic alcoholism.

Report of Cases

Case 1.—A single man, aged thirty-two years, was seen at the Mayo Clinic in 1940, after a period of a few weeks' hospitalization for alcoholism with which

he had been struggling unsuccessfully for approximately ten years. His general physical state was good and he was superficially clear in his thinking except for a lack of appreciation of the hold alcohol had upon him. This was demonstrated by the illusory opinion that he still could "beat the game."

The past history was the usual picture of alcoholic defeats with a record of having handled many worthwhile jobs, including that of salesman, radio program manager, and government employe, only to lose these positions successively through his alcoholic bouts. There was no single or unusual etiologic factor disclosed in a review of the dynamics which preceded the alcoholism. Intelligence and general abilities were well above average. Although he suffered somewhat from competition and self-comparison with an older brother, this was more apparent than real, and there was never any lack of affection or interest in the patient on the part of the various members of the family. More justly it might be said that his drinking had been begun as a means of enhancing the conviviality of a socially conscious adolescent. The sense of freedom and increased social poise which he had experienced suggest that underlying conflicts and feelings of inferiority definitely had been present but probably no more than in the average adolescent. The next ten years had been marked by gradually increased dependence upon alcohol mixed with periods of abstinence, remorse, self-criticism for opportunities, and time wasted. The development of mental mechanisms of rationalization and projection, through which he was able to soften the pain of his failures by placing the blame on others, had marked the introduction of a more serious phase of the alcohol problem.

From 1936 to 1940 numerous hospitalizations were instituted with temporary benefit, even to the extent of abstinence from alcohol for one year. However, he always had entertained the idea, which later became almost an obsession, that he eventually would be able to drink socially. (One of the primary principles of the Alcoholics Anonymous program is the simple acceptance as a fact that the member can never imbibe again.)

The results of examination at the clinic in 1940 were objectively negative. Although his history was highly suggestive of that of a psychopathic personality, we were unable to limit the diagnosis to more than "chronic alcoholism without psychosis."

In the next fifteen months he spent two visits, totaling approximately six months, in a state hospital. Although these were followed by fairly long periods of abstinence, there was never any recognizable attitude of personal security noted in the patient, but rather a somewhat defiant, quasi-arrogant manner,

From the Section on Neurology, The Mayo Clinic, Rochester, Minnesota.

as though he were trying to convince himself that all was well.

His affiliation with Alcoholics Anonymous early in the autumn of 1941 is too recent to draw conclusions therefrom. However, his personal reaction to the crisis created by his admission of defeat by alcoholism, his co-operation with the group in these few months, his endorsement of the program and honest evaluation of himself indicate definite improvement from a psychiatrist's viewpoint. For these reasons this case, which is the prototype of so many other cases, seemed worth reporting.

Case 2.—In February, 1941, a married man, aged forty-nine years, was admitted to the Neurologic Service of St. Mary's Hospital in an intoxicated condition. He had consumed approximately a quart of whiskey per day for three or four days. No remarkable precipitating factors could be elicited for the periodic drinking which had become progressively more frequent since 1930. His business had become more demanding during that period with acquisition of more responsibilities, both professional and social, and it was thought these might be working him into a trap, from which he felt alcohol offered the only escape. General examination demonstrated dehydration, the usual tremors, and ataxia of the toxic type. There also was a bilateral horizontal nystagmus which disappeared with the other neurologic signs as the toxic state cleared. The mental status was that of a tense, mildly irritable, apprehensive individual, whose restlessness caused him to make glib and meaningless promises in the hope of leaving the hospital to obtain more alcohol. This restlessness largely disappeared with the institution of an eliminative and adequate dietary regime, supplemented by the usual vitamins.

No intensive probing of psychogenic factors was made but a rather complete evaluation of the immediate situation was made with recommendations for more judicious expenditure of his energies in his work and recreational endeavors. His physical status, emotional control, and apparent insight were commendable at the time of his dismissal ten days later. In spite of this temporary relief, he relapsed within a few days and fully resumed his former habits, which now began to interfere seriously with performance of his business duties. Through the offices of his family and friends he enlisted the aid of Alcoholics Anonymous, went through the detoxifying hospitalization period, and adopted the program completely.

When seen in December, 1941, he had resumed the full responsibilities of his former occupation and convincingly declared he had begun to enjoy life again. Proudly he stated, "I've been dry for seven months"—by far the longest "dry" period in the past ten years.

Comment

It may seem premature to report these cases at the present time since the periods of abstinence are still well within the danger zone. As I have indicated, the patient in case 1 enjoyed a period of abstinence of almost a year during a long period of alcoholism. However, I am of the opinion that at no time in the past fifteen years has he ever demonstrated an attitude (supported by observations of friends) which has been as favorable as the one recognized at present. In other words, it would seem that there is some actual change in personality. This, of course, is the ultimate objective of every physician, psychiatrist or psychoanalyst in the treatment of chronic alcoholism. The resultant change may represent merely a reorganization of habits which exclude alcohol, yet a profound reorganization of character, disposition and temperament,

and any other features that go to make up personality, may take place. I will frankly admit that during the period of my active treatment of these two patients, I considered one of them as a psychopathic personality—a constitutional psychopathic inferior—who presented a hopeless task if one were thinking of cure. The incidence of chronic alcoholism in psychopathic personalities, whose outstanding defect is that of a lack of emotion, that is, emotional immaturity, is much higher than the incidence of alcoholism among neurotic or psychotic persons. It is reasonable to assume that many of the benefits obtained through the self-organized, self-administered, coöperative organization, are derived from the opportunity it offers the individual to accept responsibility. Furthermore, he is given the opportunity to become emancipated from a state of emotional immaturity through his constructive efforts in behalf of the society. In other words, the responsibility and demands of coöperation are probably of first importance in his delayed maturation. The most rational program and sympathetic counsel of any physician is liable to fail if he is dealing with an individual who is still struggling to assert himself in a judicious manner, or to emancipate from parental or other protective influences even at an age of forty or fifty. So far as I can determine there is no miraculous nostrum handed to the patient on a silver platter by Alcoholics Anonymous. The organization demands a great investment of intellectual, emotional, and physical energy. Convalescent members are "on call" at any time in the twenty-four hours to go to the bedside of a patient who has called for help. It is his job to administer to that patient with the judgment of one who has recently experienced the same anguish and whose primary objective is to "bring his patient through." The qualitative as well as the quantitative results that have been accomplished by the organization locally and nationally, leave little doubt that the rapport and even insight developed in the patient by his exalcoholic brother are considerably more effective than those induced by the counsel of his physician.

It would seem at the present time that Alcoholics Anonymous has much to offer the medical profession, by taking some of the highly refractory cases of chronic alcoholism off its hands. The medical profession, however, has reciprocal benefits to offer the organization. Alcoholics Anonymous has requested assistance in properly effecting detoxification of the new members preparatory to establishment of their program. Hospitals and physicians in metropolitan districts have given valuable assistance in working out these objectives. There are about 8 to 10 per cent of the individuals accepted in Alcoholics Anonymous, however, whose alcoholism may be symptomatic of an underlying organic condition such as tumor of the brain, convulsive disorder, manic-depressive psychosis or less obvious involvement of the neuromuscular system. It is the hope of the executive board of Alcoholics Anonymous to be able to establish local medical consultation facilities to which they can turn for counsel in these more difficult cases. It seems logical that such an agreement should work to the benefit of both organizations.

CLINICAL-PATHOLOGICAL CONFERENCE

◆ MINNEAPOLIS GENERAL HOSPITAL ◆

Frank C. Andrus, Pathologist

Presentation of a Case

DR. FRANKLIN MOOSNICK: The case is that of a fifty-six-year-old white man who was admitted for the last time on December 30, 1941. His present illness dated back to December, 1940, when he developed back pain which he described as lumbago. It was a catching pain which prevented him from straightening upright. He saw a chiropractor who gave him treatments which made him feel better. However, the pain got more severe and further adjustments were of no benefit. A few weeks later he began to notice discomfort in the heels of both feet. He thought it might be due to his shoes so he padded them but got no relief. The pain grew worse and became stabbing in character. It gradually spread to involve his ankles, calves, knees, and legs during the next six months. A few weeks after the onset of the pain, he began to notice edema of his ankles particularly in the evening which disappeared, however, with bed rest. This went on for a period of five or six months. During this time the pain had grown to such severity that he was unable to keep his covers over his feet at night.

DR. E. T. BELL: His main complaints at that time were confined to the pain in his legs?

DR. MOOSNICK: Yes. About the same time, August, 1941, he began to notice difficulty with his bladder, i.e., frequency, occasional incontinence, and difficulty in starting the stream. These symptoms were not constant. About a month before admission, November, 1941, he began to have trouble keeping his balance properly. He noticed that he would stumble frequently, mostly to the right side. This kept growing worse until in the course of a week, he fell as many as four or five times a day and had to take to his bed. He had no associated vertigo or faintness. He also felt that he could not control the right side of his body. He knew what he wanted to do with his feet but they would not respond. With that he noticed changes also in his right arm and right half of his body. He took to bed with these symptoms but they continued to grow worse. A week before admission he noticed diplopia. He had a little tinnitus with ringing and a crackling sensation in his ears at this time. About two weeks before admission he noticed difficulty in his speech. With that story, he came into the hospital.

His past history was not remarkable. Family history revealed tuberculosis, cancer, and hypertension. His mother had died of cancer of the stomach at the age of sixty-three years. He had had heart trouble

during his adolescence being particularly bothered with missed beats and generalized weakness so that he was unable to indulge in activities with boys of his age. He had had no specific treatment at that time and no definite diagnosis had been made. The only other illness he had had was smallpox in 1922.

At the time of admission he was found to be well developed but extremely pale and quite weak. He had evidence of fairly marked weight loss. Physical findings included generalized lymphadenopathy. The nodes were felt to be discrete, firm, and nontender, and had a tendency to appear in chains. Neurological examination revealed the pupils to be equal and regular and to react to light. Some nystagmus was noted in the left eye, particularly on upward or outward gaze. The chest, thyroid gland, neck, and prostate were normal. There was no tenderness on pressure over the spine. He could not move it actively but suffered no distress in that region. There was slight edema of his ankles. The reflexes on the right were slightly more active than on the left, particularly in the legs. The Babinski reflexes and the Hoffmann sign were negative. There was general loss of muscle tone over the entire body most marked over the right leg and slightly less marked in the right arm. He had diminished sensation in both legs to pinprick and touch. The vibration sense was diminished and position sense was equivocal.

Laboratory Findings: The Rytz and Kahn were negative. The hemoglobin was 68 per cent, the erythrocyte count 3,800,000, the leukocyte count 8,200, and the differential count 85 per cent neutrophils, 12 per cent lymphocytes, and 2.5 per cent monocytes. The urine had a specific gravity of 1.022 and contained a faint trace of albumin. A number of x-rays were taken which showed nothing of importance.

His hospital course showed a progression of his symptoms and a general downhill course. The nystagmus increased. He developed left facial weakness and his hearing became decreased, particularly in the right ear. The right arm became much weaker. From paresis in the beginning, he went on later to palsy. He was unable to stand or to move about his bed. The reflexes on the right side over a period of a couple of weeks became more active. However, there was no spasticity at any time.

Spinal puncture was done and showed an initial pressure of 120 mm. Prompt jugular response was obtained on the left and none on the right. The

final pressure was 50 mm. Examination of the spinal fluid revealed 1 to 2 cells, 85.6 mg. of protein, and a positive Nonne test. A first midzone gold curve was obtained. His left eye developed a ptosis and later a total palsy so that he could not open his eye. He developed proptosis and paresis of all the extra-ocular movements on that side. A lymph node biopsied showed a malignant lymphoblastoma of the Hodgkin's disease type.

His speech became more slurred until it was difficult to understand. He began to run a high grade fever after two weeks which finally rose to 108 degrees on the day of his death.

In summary, here is a man who was previously well. In the course of a year, he develops signs of peripheral neuritis of both legs gradually involving much of his body. He then had associated bladder symptoms which we associated with peripheral neuritis. Then, shortly before death, he developed right hemiparesis, and then paralysis of his left eye.

DR. G. E. FAHR: What about the lymph nodes?

DR. BELL: They showed Hodgkin's disease. The question is what explains this neurological picture.

DR. MOOSNICK: It was our clinical impression that perhaps this man had Hodgkin's involving the lymph nodes around the peripheral nerve systems and then rising to the brain giving the cerebral picture. We thought it logical.

DR. BELL: You put the Hodgkin's where it was needed! To account for all his symptoms, he would have to have a lot of spread of the Hodgkin's.

DR. MOOSNICK: Well, he had lymph nodes all over.

DR. BELL: This is a pretty hard case to diagnose clinically, but it is one of great interest. If you see the postmortem picture you can see the whole story. But it was very puzzling from the clinical picture.

Autopsy Findings

DR. H. E. MORTENSBAK: At the time of autopsy, the body was that of a poorly developed and poorly nourished man. There was no jaundice or edema. The right pupil was wider than the left.

The peritoneal cavity was negative. The appendix was normal. No abnormalities were noted on examination of the spleen, liver, gastro-intestinal and biliary tracts, or the pancreas and adrenal glands. The genitourinary tract was also negative.

Chains of enlarged lymph nodes were found in the cervical, axillary, and inguinal regions. Those in the abdominal and thoracic cavities were not particularly enlarged. The scalp, skull, and meninges appeared entirely normal. The vessels at the base of the brain and over the convolutions were examined carefully but showed no gross change. On serial section of the brain, a number of small areas of softening were found. A fairly large area of softening and discoloration was seen in the lower part of the left side of the pons. The spinal cord and the cauda equina were also removed and they revealed small scattered areas of softening, the cause of which was not apparent.

DR. BELL: There was softening in the pons but no lymph nodes in the cranial cavity or spinal canal. You still don't have any Hodgkin's to explain all these neurological symptoms.

DR. FRANK C. ANDRUS: Microscopic examination of the organs revealed a very striking and severe change. In all of the tissues examined, including the kidneys, prostate, the myocardium, lymph nodes, brain, pons, spinal cord, and cauda equina, numerous small arteries showed peri-arteritis nodosa. The adventitia and muscularis were infiltrated with large numbers of mononuclear leukocytes and neutrophils producing great thickening of the wall with reduction in the size of the lumen and not infrequently thrombosis of the artery. Eosinophiles were not prominent in the lesions just as they were not increased in the peripheral blood. Only the very small arteries, under 1 mm. or so, appeared to be involved; thus, the nodular thickenings were not apparent upon gross examination. This also accounts for the fact that no infarction was found in the kidneys, prostate, and other organs except the brain. The softening in the central nervous system was clearly due to infarction. When we examined the cauda equina, we saw the reason for the peripheral neuritis. The vessels which accompany and nourish the spinal nerves and the nerve rootlets are involved and the pain is due to their ischemia. Thus, the symptoms of peri-arteritis nodosa are not primarily due to the disease itself but to the infarction and ischemia of the various organs supplied by the affected arteries. This explains why the symptoms encountered in this disease are so many in number and so varied. Not uncommonly, particularly when larger arteries are involved, the attention of the clinician is directed especially to the heart, the kidneys, or the intestine and the patient dies with the symptoms of coronary sclerosis, uremia, or intestinal infarction. In this case, the nervous system, although not the only one affected, produced the predominating symptoms. Eosinophilia is rather common in these cases but is not always present.

The etiology of this disease is entirely unknown. Bacteriological studies and animal inoculations have not yielded any information. We believe that it is infectious in nature and, in the absence of any demonstrable bacteria, presumably due to the filterable virus. No known treatment is of benefit. A few cases have been diagnosed prior to death. The diagnosis may occasionally be established if cutaneous nodules are palpable and biopsies are done. The disease itself does not appear to be always fatal; of 101 reported cases, 10 per cent recovered. Some cases, the diagnosis of which was established by biopsy, have remained well for some years. I remember seeing one case a short time ago where the patient had vague muscular pains and aches and an eosinophilia. A biopsy of the muscle was obtained hoping to establish a tentative diagnosis of trichiniasis. This also turned out to be peri-arteritis nodosa. We have been looking for other cases but were thrown off by the picture of Hodgkin's disease in the lymph node.

On reviewing the sections of the biopsy of the lymph

node, I found that I had failed to notice one small vessel at the hilus of the node which showed the typical change of peri-arteritis nodosa. I saw the picture of Hodgkin's disease in the lymph node and looked no further.

DR. FAHR: Is this change seen in the cauda equina common?

DR. BELL: It is pretty common in the peripheral nerves. The neuritis is due to lesions of the arteries supplying the nerve trunks. The lesion cuts down the blood supply to the nerve tissue and that is why the patient develops the peripheral neuritis you saw here. This is the type of case you don't see very often, but there are instances of peri-arteritis nodosa in which the chief manifestations are neurological.

DR. FAHR: Did you know about the peri-arteritis nodosa before you looked at the sections.

DR. ANDRUS: I missed the one vessel I showed you in the lymph node which was biopsied. I found the Hodgkin's disease and didn't look any further.

There has been a collection of eighty-seven cases published in the English literature and a list of the organs in the frequency of their involvement. The kidneys ranked highest, almost constantly being in-

involved. The next in order were the heart, liver, spleen, and lungs. I think that many of their autopsies must have been incomplete because they list peripheral neuritis as being the common symptom but did not demonstrate the lesion in the peripheral nerves.

DR. FAHR: That is why there are so many people with symptoms—so few pathologists find arteritis because they don't examine the nerves.

DR. BELL: How common is hypertension?

DR. ANDRUS: It was noted in forty-six of the 101 patients and not infrequently it takes the acute, fulminant course. There seems to be a correlation between the patients who have renal lesions and the hypertension.

DR. MOOSNICK: Is it often possible to palpate nodules along the peripheral arteries?

DR. BELL: Cutaneous lesions and nodules are found in only about one-fifth of the patients. A node biopsy will not rule out the conditions since the portion biopsies may not have been affected by the disease.

Anatomic Diagnoses: (1) Peri-arteritis nodosa; (2) Hodgkin's disease.

DULUTH PEDIATRIC SOCIETY

O. W. Rowe, President

Arthur H. Wells, Pathologist

HYDROPS OF THE GALL BLADDER

Report of Two Cases

HENRY A. SINCOCK, M.D.

Superior, Wisconsin

Case 1 is that of a five-year-old white female whose birth history is noncontributory. As an infant she was breast fed and developed normally. Her past illnesses included chickenpox, mumps, whooping cough, and measles. Her present illness started on December 24 at 7 p.m. when the child appeared cranky and had a temperature of 102° F. An enema was given at that time. On December 25, the child played about but occasionally complained of stiffness over the area of an old scar resulting from a drained suppurative lymph gland in the left cervical region two years previously. A mass the size of a walnut developed over this area and the stiffness of the neck became worse. The patient was seen December 26 because this swelling in the neck was larger and there seemed to be a similar swelling starting on the other side of the neck. Over the area where the first cervical gland was swollen, there was a dermatitis resembling erysipelas, and for this reason the child was seen on December 27, when the skin condition had subsided, but there appeared small bean sized glands in the axilla and the groin. Both hands were very red. The child seemingly was much improved for the next five days. She became nauseated and vomited on January 1 and January 2. Her abdomen remained distended in spite of several enemas. On January 4,

her temperature was 99.2° F., her pulse 90, and there was a marked conjunctivitis of both eyes. The nasal passages were a little excoriated from secretions and the cervical glands were much smaller. The eardrums were normal. The tongue was reddened and sore along the edges. The tonsils were reddened but not swollen and looked much improved over the first observation, ten days before. The glands in the axilla were very much smaller. The heart was normal. There seemed to be more than normal dullness over the mediastinal area. The abdomen was distended. There was marked muscle spasm, tenderness and rigidity over the lower quadrant near the level of the navel. No rectal examination was made because of the fear of rupturing an appendiceal abscess. The skin was clean and free from infection. The reflexes were equal and normal. The urinalysis was normal. There was a leukocytosis of 41,000 with 89 per cent neutrophils. The hemoglobin was 66 per cent.

Operation: A laparotomy revealed a large mass in the right side of the abdomen which proved to be a markedly distended gall bladder with a few adhesions. It contained about 200 c.c. of clear, watery fluid. The region was explored and some enlarged lymph nodes

were found around the cystic duct. A small drain was placed in the gall bladder and held in place with two purse string sutures. One tissue drain was placed in the abdominal cavity and the wound was closed in layers with chromic catgut and silkworm gut sutures.

There were no postoperative complications. The child appeared better mentally. The pain in the abdomen disappeared. The conjunctivitis healed. The enlarged cervical glands receded. Free bile began draining from the gall bladder. The drainage tubes were removed from the gall bladder after ten days and the wound healed completely. The patient has remained entirely well for a year subsequent to her recovery.

Case 2 is that of a six-year-old male who was treated with home remedies by his parents for two weeks prior to calling a physician for what they thought was a "cold" which was hard to cure. The "cold" was accompanied by an upset stomach. The boy had a continuous fever and marked pain and distention of the abdomen. Physical examination revealed a fairly well developed boy for his age. The ears and nasal passages were not remarkable. The tonsils were moderately enlarged and there were numerous cervical glands, the size of beans. The heart and lungs were negative. The abdomen was distended and there was muscle spasm and rigidity over the gall bladder region where a mass was felt. The urinalysis was normal. The leukocyte count was 9,300, and the hemoglobin was 82 per cent. The icterus index was 28.

Operation: A laparotomy revealed a large, distended gall bladder. Its walls were grayish with slightly dark bluish hue. About 150 c.c. of very thin, slightly brownish fluid were aspirated. The surgeon, Dr R E. Christiansen, did not explore further to discover the cause of the hydrops. A drain was placed in the gall bladder and the child made an uneventful recovery. The child has remained in good health for more than a year following this episode.

Discussion

DR. CARL O. KOLBRY: What was the cause of the hydrops of the gall bladder?

DR. HENRY SINCOCK: It would appear almost certain that in Case 1 the demonstrated enlarged lymph-nodes mechanically blocked the cystic duct resulting in absorption of bile and secretion of mucoid fluid in the gall bladder. With subsidence of the generalized lymph-adenopathy, the cystic duct became patent. Since the condition was transient, the same explanation apparently holds for both cases.

DR. ARTHUR H. WELLS: Was a heterophile antibody test done on either of these cases?

DR. SINCOCK: A heterophile antibody test was not done. No hematologic evidence of infectious mononucleosis was noted. Any condition causing an obstruction of the cystic duct might cause hydrops of the gall bladder. This disease is indeed rare in children.

VON GIERKE'S DISEASE OR GLYCOGEN DYSFUNCTION

Presentation of a Case

R. E. NUTTING, M.D.

Duluth, Minnesota

A male child, eight years of age, was observed from the age of five months. His birth history was normal. The baby weighed eight and a half pounds at birth and was born of healthy parents. An enlargement of the abdomen was noted at birth. At one month there were attacks of severe abdominal pain causing the baby to cry for long periods and to be exceedingly restless. Formula feedings were given from birth. Rather forceful vomiting occurred at two months. In spite of this, the baby made an adequate gain and at five months (when first seen), he weighed sixteen pounds, twelve ounces.

Physical examination revealed a markedly enlarged liver. Its edges extended down to, and slightly below, the level of the umbilicus, causing a protruberance of the abdomen. In other respects the baby was perfectly normal. The child has been under fairly close observation since that time. His fasting blood sugar curve has averaged around 60 mg. per 100 c.c. of blood. On administration of glucose, the blood glucose concentration curve was high and prolonged. The giving of

epinephrine did not increase the blood sugar. The blood cholesterol was 236 mg. and the chlorides 503 mg. per 100 c.c. of blood. The heart was always normal in size.

The child continued to have very severe seizures of abdominal cramps which seemed to be rather spasmodic in nature. Sedatives helped to some extent but would not completely relieve these spells. Various dietary regimens failed to make any appreciable change. Except for his rather small stature, the boy has developed in a normal manner and now weighs forty-three pounds and measures forty-five and a half inches. The liver enlargement has remained proportionately the same. However, during the past few years the frequency and severity of the abdominal attacks have been declining until at present he has not more than three or four comparatively mild episodes each year. His general health has been good, with the exception of frequent upper respiratory tract infections due to large, infected tonsils, which were removed this spring without event. He has been attending school and engaging in almost normal activities for a boy of his age.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF THE MINNESOTA STATE MEDICAL SOCIETY

By ARTHUR S. HAMILTON, M.D.

Minneapolis, Minnesota

(Continued from February issue.)

Second Semi-Annual Meeting

The *second semi-annual meeting* of June 14 and 15, 1870, was held at Winona in the hall of the Normal School. Dr. Willey presided.

For the Committee on Publication Dr. C. H. Boardman, chairman, reported that an abstract of the transactions together with the Constitution and Bylaws of the Minnesota State Medical Society, and the Code of Ethics of the American Medical Association, had been selling at a cost of ten cents per copy, which seems very cheap for what Dr. Stone in his journal called the most handsomely printed transactions of a society he had ever seen.

Dr. Staples demonstrated an apparatus of his own construction, "having for its object a greater facility in obtaining apposition of the fragments *without deformity*, in cases of fractured clavicle." Dr. Staples claimed originality for his treatment on the point of pressure made upon the angle of the scapula. Considering the multitude of different forms of apparatus devised for treatment of fracture of the clavicle, it is difficult for the editor to say just how far Dr. Staples' method represented a new idea, but it is certain that the apparatus which he presented at that time, and which he had described in full in the *North-western Medical and Surgical Journal*,[†] is very similar to the apparatus still employed for that purpose.

At this meeting developed the controversy over the admission of women, which is given in full under the heading of "Admission of Women to the State Medical Society."

To return to the regular proceedings of the Society at its second semi-annual meeting, almost the entire session was given over to a discussion of epidemics which had appeared in different towns and their relation to atmospheric conditions, drainage, and cultivation of the soil as well as to the much-discussed Minnesota climate. Reports from different districts varied greatly as to the occurrence of epidemics but no common causes were agreed upon. In the early stages of the session Dr. Hewitt clearly outlined the possible relation of atmospheric conditions to the various epidemics prevalent and strongly urged concerted action in the search for the local conditions on which health depended and, in the course of his remarks, said: "There are some parts of the state (such as Rochester) which are supposed to have something *peculiar* in their air or water; and, if this could be conclusively determined, *aye* or *no*, a key would be obtained which might enable us to unlock much that now baffles us, in the *absence* of such knowledge."

One session was devoted to asking and answering questions concerning personal experiences and especially to a consideration of "climatology" and "phthisis

[†]N. W. Med. and Surg. Jour., Vol. 1, No. 3, p. 99.

pulmonalis," including the presence of ozone and *miasm*, and the influence of the latter as a cause or modifier of disease. Dr. Mayo's answer to the questionnaire as to ozone is suggestive: "I believe that many of my professional brethren are, like myself, uninformed on this point. I have tried to ascertain what ozone really is, or whether really it exists as a separate and distinct entity, but, I have never succeeded to my satisfaction."

Dr. Murphy said he had lived in the state twenty-four years and there had been a great change in the climate, the winters being much more mild and the winds not nearly so strong. Others thought there had been no material change. Practically all were agreed that phthisis pulmonalis almost never originated in the state. Some thought the climate was favorable in all cases, but others limited the effect to incipient cases, and felt that those coming with well-developed phthisis died here as elsewhere.

Drs. Murphy and Sheardown gave their personal experiences, both having come to Minnesota with well-developed tuberculosis and having made subsequent extraordinary recoveries. Dr. Mayo ventured to ask Dr. Murphy whether he was quite satisfied that when he came he labored under actual and unmistakable *phthisis pulmonalis*. Dr. Murphy maintained that his condition had been diagnosed by capable men, and he was positive as to the situation, having increased from 136 to 226 pounds in weight. Dr. Sheardown reported that he had even coughed up a portion of the tuberculous mass from his lung and nevertheless had recovered. He came to Minnesota very thin and now weighed 200 pounds.

In connection with this discussion on climatology, the following paragraphs from the *Northwestern Medical and Surgical Journal*† are interesting:

"We would call the attention of all the physicians and scientific men in the state to the circular just issued by Dr. C. N. Hewitt, *Member for Minnesota of Committee on Climatology and Epidemics*, *American Medical Association*, and Dr. W. W. Sweney, *Chairman State Committee on Climatology, Hygiene and Epidemics*.

"Claiming, as we do, for our state, a total of partial exemption from many of the worst forms of disease, we cannot overestimate the value and importance of the work thus undertaken by Drs. Hewitt and Sweney. It behooves each member of the Association to read the circular carefully; to note down the answers, which *his* experience may give, to each question, in its numerical order; and to forward them at once to the address of the above-named gentlemen, Red Wing, Minnesota."

Edwin Jackson of Saint Paul, who was in attendance, later wrote the *Northwestern Medical and Surgical Journal** on the subject of the changing climate, and thought the variations noted were more apparent than real, that no reliable evidence as to such change existed, and that the views expressed were largely based on *remembered impressions*, and noted that such extremely subjective evidence, as a rule, can carry very little weight.

The following extract from an article by Brewer Mattocks,** entitled "Has the Climate of Minnesota Changed Within the Past Fifteen Years," presents some interesting views.

"It is not an uncommon thing to hear old residents of the State assert, upon *their own experience*, that our winters have become much warmer during the time they have resided here. As a general thing, this assertion is simply the result of individual sensation. For instance, perhaps one-half of the business men of Saint Paul came to Minnesota originally for the benefit of their health. Suffering from tuberculosis, they came here weak, bloodless, and, perhaps, from a warmer climate. In such a physical condition it would not be thought strange that the cold of the first *few* winters would be exaggerated, so far as their sensations were concerned.

"As these person improve in health and increase in weight, of course they do not notice

†N. W. Med. and Surg. Jour., Vol. 11, No. 3, Sept., 1871.

*N. W. Med. and Surg. Jour., Vol. 1, No. 2, p. 31.

**N. W. Med. and Surg. Jour., Vol. 1, No. 2, p. 76.

the cold as they once did—they do not suffer from it so much. Take, if you please, the experience of the writer as an instance. Fifteen years ago, when first we came to Minnesota, from 'circumstances over which we had no control,' we sawed and split the wood for the family out of doors; we also slept *alone* in a part of the house which was never heated. This experience convinced us 'that the climate of Minnesota was not fit for a white man to live in.' But time has dealt kindly with us—we no longer saw our own wood, and we now enjoy the luxury of warm sleeping apartments. Our surroundings are changed, but not the climate. We think this homely, though personal, illustration is pertinent. We think that many, like ourselves, enjoy the change of circumstances, rather than the change of climate."

In the course of his article, Dr. Mattocks also quotes from the *Philadelphia Medical and Surgical Reporter* as follows:

"The climate of Minnesota, according to recent information, has entirely changed within the last fifteen years, since the forests have been cut down and twelve million acres of wild land have been brought under cultivation. In consequence of this change, it is now doubtful whether the climate of Minnesota is any longer beneficial to consumptive individuals. * * *

"The Secretary of the Young Men's Christian Association in Saint Paul, in a letter to the *Washingtonian* makes the following statement: 'Our Association has spent hundreds of dollars the past year, without counting the days and nights of watching, in providing homes, comforts and coffins for Christian young men who have come here from Boston in search of health, but in reality can only find a grave in the beautiful lot of the Young Men's Christian Association in Oakland Cemetery.'"

Early in the course of the June, 1870, meeting, the Society offered a prize of \$50 for the best essay on the subject of "Malaria, Its Causation and Effects upon the Diseases of Minnesota," and a similar prize for the best essay on "Uterine Diseases in Minnesota."

Dr. Stone then offered a prize of \$100 for the best essay on "The Benefits of the Climate of Minnesota to the Consumptive." All competition was limited to members of this Society. Since Dr. Stone insisted on a proprietary interest in all manuscripts submitted, one may suspect he had some interest in providing material for his new journal.

That politics played a rôle in the State Society at this early date is evidenced by an editorial of Dr. Stone in the *Northwestern Medical and Surgical Journal*.^{*} Reference is there made to a feeling that Saint Paul had already been honored with the presidency, which ought now to go to the southern part of the state. Drs. Hill, Ames and Goodrich were mentioned as available men from Minneapolis, but the Society was urged to find its leaders from the south and the names of Drs. Franklin Staples, W. W. Mayo, C. N. Hewitt, C. P. Adams and Francis H. Milligan were suggested from that territory.

The *Journal* for February, 1871, felicitated the Society on the large attendance at the annual meeting, and on "a spirit of harmony which rather surprised the croakers of our first meeting."

Third Annual Meeting

The third annual meeting of the Minnesota State Medical Society was held at the Merchants Hotel in Saint Paul, February 7 and 8, 1871. The rapidly failing health of the secretary, Dr. E. H. Smith, had compelled his return to his old home in Connecticut, and Dr. Charles E. Smith, of Saint Paul, had accepted the position so made vacant. Dr. Willey, in his opening address, thanked the Society for again having honored him with the presidency, and referred to his own uncertain health which would compel him to retire from the position. He also referred to the passage at the last session of the Legislation of a Registration Law entitled "An Act to Provide for the Collection and Publication of Statistics." Hon. Pennock Pusey, Assistant Secretary of State, who appears to have compiled the law from those already enacted in Michigan and Massa-

^{*}N. W. Med. and Surg. Jour., Vol. 1, No. 7, p. 226.

chusetts, was largely responsible for its passage, and was made the Commissioner of Statistics.

The Membership Committee reported in accordance with the list given at the end of the volume.

It was moved that a committee of five be appointed to nominate officers for the ensuing year. Dr. Sheardown wished the nominations to be made by the Society-at-large, but this motion was lost. The Nominating Committee, through its chairman, Dr. C. Powell Adams, submitted a majority report including Charles N. Hewitt for president.

A minority report was in favor of Dr. Franklin Staples of Winona, for president, with the remaining officers as in the majority report. Dr. Staples was ultimately elected president, with the other officers. (See table at end of this article.)

In his inaugural address, Dr. Staples referred to his predecessor, Dr. Willey, as follows:

I cannot expect to fill the office of my predecessor with equal acceptance to the profession. Gentlemen, I need not remind you of what we have enjoyed, as a Society, under the able management of him who has presided over our deliberations since our first organization; a gentleman whose ability and integrity, whose noble qualifications of head and heart, so justly entitled him, not only to that place which he holds in the affection and regard of the medical profession of our own State, but to the honorable position which he holds in our national Society [vice president of the American Medical Association, 1870], and in the profession of the country.

Gentlemen, the name of Dr. Samuel Willey will be cherished among us, as long as we admire culture, and have respect for professional excellence in medical men. Would that he had more physical strength and a better promise of length of days.

The Committee on Finance recommended the annual dues to be fixed at \$2 per member. Dr. Blood moved that the dues be \$1. This motion was lost and the original report accepted.

Dr. Stone introduced a motion that the fee for examination for life insurance by members of the Society be fixed at \$3. After a lively discussion the motion was laid on the table, on the ground that the local societies could better deal with this situation.

Dr. Stone also introduced a resolution pertaining to a law governing dissecting, but no information is given concerning it at that time, beyond that it was read and laid on the table.

Another motion made by Dr. Stone called upon the president to appoint a committee of three to draft and present a bill to the present Legislature for the enactment of a medical law in the state. This was strongly opposed on the score that it was premature, would fail and would hamper future effort, and was finally laid on the table, and made a special business for the following day. I have not been able to find anything further in regard to this, and the matter was evidently not pressed.

Drs. Mayo and Stuart, from the Committee on Prize Essays on Uterine Diseases in Minnesota, and on Malaria, respectively, reported no essays received. Dr. Adams desired to be relieved of the One Hundred Dollar Prize Fund, which was finally left in the hands of the treasurer. Later in the meeting, Drs. Wharton, Willey and Hewitt were appointed a committee to arrange for prize essays for another year, and reported the following:

Ozone, the chemical and other evidences of its presence in the atmosphere, and its influence in causing, modifying and preventing disease.

The Pathological Changes Induced in the Kidney and Its Secretion by Scarlatina, with chemical and microscopic preparations, in illustration thereof.

For the best essay on either of these, \$50 in money.

Original appliances and methods of treatment for fracture of bones, with at least three illustrative cases.

Prize on this a fifty dollar microscope.

The Committee on Epidemics, Climatology and Hygiene reported through its chairman, Dr. W. W. Sweney, and the Committee on Surgery, through its chairman, Dr. Staples, and the latter report appears in the appendix to the Transactions and contains some interesting information. Under Malignant Diseases, Dr. F. H. Milligan of Wabasha reported six cases of cancer of the uterus, and remarked as follows: "In my opinion, our climate, from some cause which I do not understand, is favorable to the rapid termination of malignant diseases." Whether this Delphian comment was meant to be favorable or otherwise to the vaunted Minnesota climate, who shall say?

Goiter was reported as comparatively prevalent, and Dr. J. B. McGaughey, of Winona, attributed the cause to calcium and its salts in the water. Drs. Milligan, of Wabasha, and Blood, of Owatonna, found goiter most common among the Germans, while Dr. Redmon, of Preston, thought Norwegians most susceptible and gave soft water to drink and iodides internally and externally as his treatment.

Erysipelas was not uncommon but "more amenable to treatment here than in other localities."

The great majority of surgeons in the state gave chloroform as their favorite anesthetic since it was both pleasant in administration and prompt in action, but it was generally admitted that ether was the safer.

A further report in the appendix of the Committee on Practical Medicine gave some interesting views on typhoid fever. There was evidently a considerable lack of clearness in the views held as to the nature of typhoid fever, and Dr. Galloway spoke of it as "so-called typhoid fever." Dr. Galloway also stated that this malady appeared to be endemic in most parts of the state, while, on the contrary, it was very rare in the older communities of the East, and was seldom seen except where "miasma abounds." It had been stated by competent observers that there was invariably an outbreak of the fever among recent settlers, especially those locating their farms upon the prairie. The view was expressed that there was probably no single factor which was capable of originating typhoid, and "the only apparent exception to this statement is that those advocating the doctrine of contagion allege that the fecal discharges of typhoid patients contain the typh-poison, and that they create the same disease in those subjected to their influence."

Dr. Galloway reported an epidemic of about 250 cases which had prevailed during the last fall and winter in Rochester and its neighborhood, and of these some twenty-five terminated fatally. After considerable discussion of the terms "intermittent," "malarial" and "typhoid fever," it was the author's final conclusion that the cases which he had reported represented typhoid fever in an individual already affected with chronic malarial poison, whereas what he called "pure, uncomplicated typhoid, or enteric fever," was of very rare occurrence in this region.

In the same report reference was made to a local dispute concerning the nature of certain sore throats, and the author spoke of diphtheria as "of an almost invariably fatal character."

(To be continued in April issue.)

President's Letter

I.

I HOPE that members of our Association will at this time take an especial and personal interest in the teaching of first aid. A wide knowledge of first aid is essential especially in the work of the Red Cross and in civilian defense. Air raid wardens, victory aids, defense companies, voluntary firemen and police are required to have a knowledge of first aid, and volunteer workers need instruction.

It may not be possible for a busy physician in a small community actually to conduct classes himself, but he can at least be present occasionally to act as consultant to the lay instructors. It would be better, of course, if all classes could be conducted by physicians. However, under present circumstances lay instructors are necessary. By acting as consultant the physician can supervise the course and can indicate how, in his particular practice, he would like to have his prospective patients handled, how much he would like to have done, and what not done, as a part of first aid practice.

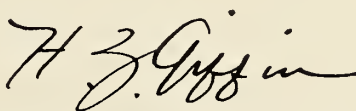

Our Committee on First Aid has been an active and efficient one for years under the chairmanship of Dr. A. B. Stewart, and will continue to function aggressively under the chairmanship of Dr. J. S. Lundy. Classes have been conducted in various communities throughout the state for some time. Lectures, demonstrations and quizzes have been given. Dr. Lundy has large and enthusiastic classes, and devotes one-half hour a week to oral examination of pupils by the quiz method, which is broadcast over the local radio station; this in the nature of an experiment. Unexpected public enthusiasm has been shown for this program. Obviously the method could not be adopted where the instructor might be accused of "advertising." A representative of the county medical society, the local health officer, a physician not in private practice, could conduct such quizzes in most communities. Whether or not such a broadcast is advisable should be decided by the local medical society.

Experience shows that after a physician once acts as instructor he becomes so interested that he rarely discontinues the work. To eliminate controversy in classes it is advisable to follow the Red Cross First Aid Textbook even though differences of opinion may arise concerning certain procedures. It is best not to air these differences before the class. It is most important to teach "what should not be done" in an emergency as well as "what should be done." Accidents have assumed such importance that a more widespread knowledge of first aid among the laity not only proves useful in emergency but acts as an element toward accident prevention. First aid instruction makes the public not only accident conscious but earnest in accident prevention.

There is no lack of general interest. The demand is for more physicians who will act as instructors and consultants, and those who can so act will, I am sure, offer their services to the local organizations. In some communities a certain amount of give and take and calm coöperation may be necessary in view of the number of organizations supervising courses in first aid and the natural tendency of these efforts to overlap. I am sure, however, that the officers of these organizations can arrive at a mutually satisfactory division of credit and responsibility. The local defense councils, the Red Cross, emergency patrols of Boy Scouts, and local safety councils are among those concerned. The Committee on First Aid of the State Association would like to be useful and will be glad to assist. Anyone interested should communicate with the chairman. The local medical defense committee should keep in close touch with the councilor of the district, who is also chairman of the District Health Section of the State Welfare Defense Committee.

II.

Medical organization for other phases of civilian defense is now taking form. It is to be hoped and expected that those in charge of the work of local defense councils will utilize existing facilities which have been functioning for years. The local health officer as representative of the State Board of Health and also an official representative of the local medical society should be members of local defense councils. Officers of local societies should see that proper representation is obtained. The organization of local emergency medical services will doubtless be placed in the hands of committees of physicians. The local health officer, where he is properly qualified, will be a logical chairman for such a committee because he is familiar with the functioning of the several divisions of the State Board of Health and also with the facilities of the community. Coördination with the Medical Battalion of the Minnesota Defense Force will be necessary. The task is one which will require initiative, coöperation, coördination and judgment.

THE MEDICAL TESTIMONY COMMITTEE

DR. H. Z. Giffin, president of the State Medical Association, has reappointed the entire Committee on Medical Testimony for the ensuing year. The committee was increased to six by the appointment of Dr. B. S. Adams of Hibbing. This was a very timely and fitting selection as Dr. Adams was the instigator of this most interesting movement and will be one of its most enthusiastic workers. The status of medical expert testimony in this state is excellent. However, it will require constant vigilance and guidance to keep it at this high level. Several verbal

complaints have been received by members of the committee from physicians throughout the state regarding so-called questionable testimony by some of its members. Your committee cannot listen to gossip. Any physician or attorney or judge who believes that a certain testimony by a physician should be investigated, must submit his complaint *in writing* to a member of the committee and the necessary procedure will be immediately instigated. Several cases have been reported, thoroughly studied and suitable measures taken. Your committee has received national attention and the results will be carefully noted. The *Railway Bulletin*, representing the Claim Agents of every railroad in this country, published an interesting article during the past year. A similar publication was made in *The Journal of American Insurance*, in January, 1942. This journal is one of the official organs representing the insurance companies of the United States. Railroads and insurance companies because of the many personal injury suits brought against them are vitally interested in the testimony of the medical expert. It is the duty of every member of our State Association to advise your Committee on Medical Testimony about questionable or dishonest opinions by the medical expert. Only in that way can the committee function properly to help maintain the high ethical standard in our association.

E. M. H.

MILITARY SURGEONS MEET

AT the meeting of the Military Surgeons held recently in Louisville, Kentucky, an officer of the Army Air Force gave an instructive discussion of various factors involving training of civilian personnel. He emphasized the orderly expansion of aviation medicine to keep in step with National Defense. The problem falls into two large groups: (1) personnel; (2) training personnel. A total of 30,000 pilots each year calls for physical examination of 120,000 men and in addition another 100,000 must be selected for crew members, navigators, gunners, and bombardiers. Youth is most desirable as age tends to slow up reaction time.

The student successfully passing his physical examinations together with sufficient scholastic credits begins his intensive course of training as follows: He attends a replacement center for a period of approximately five weeks where he receives his vaccinations, clothing, and fundamentals in military training. His next step is ten weeks' instruction in learning to fly and making his first solo flight. Next is the basic school of ten weeks where further instruction and flying maneuvers are participated in. At the advanced school another ten weeks is spent in air maneuvers, as formation flying, night cross country flights, lectures and demonstrations of effects and anoxia, speed and centrifugal force, low pressure chamber ascents with demonstration of the effects of high altitudes on the ears, sinus cavities and intestines. In addition they are taught uses of O₂ equipment such as masks, and the care of tanks. Air force requirements of oxygen—(a) for all flights 10,000 to 12,000 feet lasting six hours or more; (b) 12,000 to 15,000 feet lasting two hours or more; (c) 15,000 feet or over, always; (d) from ground up when the climb is 2,000 feet per minute.

Successfully completing his course of instruction, he receives his wings and a rating of pilot with rank Second Lieutenant, Air Corps Reserve.

Another interesting discussion was that given by the Assistant Medical Director of National Defense of Canada.

Duodenal ulcer constitutes the biggest medical problem. Of all non-effectives returning from overseas, 25 per cent are due to ulcer. In the World War I, ulcer was the sixth cause for discharge. Fifty per cent of the Canadian army gave pre-selective meal history; seventy-five per cent in the British army. Of those treated for ten months 50 per cent are still carrying on; 50 per cent had a subsequent breakdown and returned to Canada. Those with ulcers treated in Canada were never allowed to go overseas. Seventy per cent of these are still effective; 30 per cent had a relapse and were discharged.

According to a survey of chest examinations of 400,000 enlistment films, 1 per cent was rejected at the time of enlistment, for tuberculosis. The standards for eligibility on enlistment are: (1) negative x-ray; (2) small calcified lesions, inactive; (3) small fibrous lesions, inactive. Of those who enlisted under the above standards fifty-five have broken down. Of these, twenty-five

broke down in Canada before going overseas; sixteen with negative films on enlisting; nine with small lesions; one a calcified lesion. Thirty broke down overseas; twenty-seven with negative films on enlistment; three with small lesions; and one calcified. Of the fifty-five who broke down with tuberculosis fifty-three had acute pulmonary tuberculosis with positive sputum; nine had pleurisy with effusion; and three metastatic tuberculosis.

F. L. SMITH

PRACTICE—NOT PLEASURE

WE ALL know that the Federal Government found it necessary to inaugurate the rationing of new automobile tires and tubes, effective January 5, 1942. Our government recognizes the necessity of having physicians and surgeons' automobiles equipped at all times with good tires and tubes, and, as a result, placed all members at the head of the list as far as eligibility of civilians is concerned. We should definitely appreciate the consideration that has been given us by the government, and in no circumstances should the privilege be abused as it was in the case which is herein reported.

A certain doctor in the state, shortly after the rationing program took effect, persuaded a local rationing board that due to his profession, he was eligible for a complete set of tires and tubes. In applying for these tires and tubes he stated in his application that these tires and tubes were going to be mounted upon a vehicle used principally in his profession. Two or three days after he purchased the new tires and tubes, he and his wife left on a five weeks' vacation trip by motor. This, in our opinion, was not only a most unpatriotic act but was an actual misrepresentation of fact.

The doctors of Minnesota and the doctors of the nation cannot hope to be continued as eligible purchasers of any automobile tires and tubes if there are many cases like this. It is only fair to assume that as the various state rationing administrative offices come across cases of this type and report them to the head office of the Office of Price Administration in Washington, that the eligibility rules in so far as physicians and surgeons are concerned will be drastically changed and the majority of us will have to suffer for the wrongdoing of a few.

FREE CANCER HOME

A free home for people suffering from incurable cancer was opened, in Saint Paul, on December 8, 1941. It is known as Our Lady of Good Counsel Free Cancer Home. Situated at the corner of St. Anthony and Cleveland Avenues, it is easily accessible from any point in the Twin Cities. The building is bright and cheerful. The atmosphere of the place is one of peace and contentment. Nine Dominican Sisters, Servants of Relief for Incurable Cancer, attend to all the tasks in the conduct of the home.

Anyone afflicted with cancer, and not having the means to secure care elsewhere, will be a welcome guest at the home. The sisters in charge require only to know that the patient is poor, that he is sound mentally, and that the physician in whose charge he has been recommends him for care. No limitations are made as to race, color or creed. No limitations as to locality are imposed. The home aims to serve as many as possible, providing for them every comfort and care as generously and completely as can be done. The wards are made homelike with plants and pictures chosen for their restful effect. The sisters are all trained to give efficient and sympathetic service to the sick. It is noteworthy that their spirit of forgetfulness of self quickly communicates itself to all the patients and that their serenity of mind and heart goes far towards bringing a spirit of resignation in the minds of the patients. The guests of the home are free from financial worries. They are encouraged to think of the higher things of life, and to prepare themselves for what lies beyond.

This work in behalf of the cancerous poor was begun in 1895 on the East Side of New York, by the youngest daughter of Nathaniel Hawthorne, Rose Hawthorne, known in religious life as Mother Alphonsa. Her life and work are described sympathetically by Dr. James J. Walsh in his book, *Mother Alphonsa*, and by Katherine Burton in *Sorrow Built a Bridge*. The community that she founded in 1902 now numbers upwards of seventy-five sisters and conducts homes in New York, Philadelphia, Fall River and Atlanta. The Saint Paul home is the sixth foundation established for the religious care of poor people afflicted with cancer since Mother Alphonsa began her heroic work. These homes took care of approximately nine hundred patients during the year 1941.

The homes are supported by voluntary donations from the public. There is no solicitation of funds. Although but recently opened, the Saint Paul Free Cancer Home has been the object of much public interest and many proofs of the public's desire to coöperate have been received. The present accommodations of the home are far from being taxed, and there is room for more patients there. The sisters are glad to provide a harbor and a home for as many as they can accommodate.

Injuries to the eye occur at the rate of 1,000 a day and cause an annual loss of \$2,000,000,000, says a report sponsored by the National Society for the Prevention of Blindness.—*Science News Letter*, February 21, 1942.

SKIN GRAFTING

A Demonstration of Techniques Adaptable to the Resurfacing of Granulating Areas by Use of the Padgett Dermatome

Instead of reading a paper on the general subject of skin grafting at the 1941 meeting of the Minnesota State Medical Association Dr. H. O. McPheeters presented a motion picture on this subject.

In this cinema he emphasized the general care of burns from the time of the accident until they had been grafted and healed and showed the general care throughout that time.

Asepsis from the first to the last was the watchword, with firm pressure by use of sea sponges and tight bandages to prevent edema of the tissues and the coarse hydropic granulations so commonly seen. Soap and water cleansing with moist saline applications all the time was advised as the best way to help the separation of the dead tissue and the stimulation of fresh granulations.

A patient with a very severe and extensive gasoline burn of both thighs and lower legs (patient of Drs. Harvey Nelson and R. D. Hultcrans) presented an unusual opportunity to demonstrate the preparation and use of the "blanket graft,"* in resurfacing of large granulating areas. By the use of the Padgett dermatome sheets of skin 4 by 7 inches were shaved off 0.006 to 0.008 of an inch thick and these were then sewed together on a sheet of guta percha previously cut the size and shape of the raw area. In this way large "blankets" of skin were prepared for each leg. One hundred seventy-six square inches or 1,100 square centimeters for the right thigh and 149 square inches or 931.25 square centimeters for the left thigh. The usual sponge pressure with normal saline dressings were used postoperatively. Pictures showed both the "blankets" well healed and the patient walking eleven weeks after the first was applied.

By means of the dermatome, grafts of any calibrated thickness can be removed and with much more accuracy than with any other method. It greatly simplified skin grafting.

The donor areas were well healed in the usual time and quite rapidly assumed a normal appearance.

*This term had never been used before and as far as he was able to learn, the suggestion of sewing the many separate skin sheets or grafts together into one large "blanket" was entirely original. The total area of skin transferred in the large blanket was thought to be the greatest amount ever transferred at one time, 1,100 square centimeters.

SPECIAL FOODS FOR AGED

Special foods for middle-aged and aged people may be the next step in nutrition, according to a food survey reported to the American Chemical Society by Dr. William A. Hamor, associate director of the Mellon Institute of Industrial Research, Pittsburgh.

"New advances have been made in infant feeding and the nourishing of 20,000,000 school children," said Dr. Hamor. "With less than 2,000,000 babies born a year, infant-food manufacturers are distending their markets with lines of products for older children. It has been predicted that the next step may be foods especially for the middle-aged and aged, an advance that may be nurtured by the growth of interest in geriatrics (science of aging)."—*Science News Letter*, January 24, 1942.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association
George Earl, M.D., Chairman

PIONEERING IN SICKNESS INSURANCE

The hazards of health insurance planners were brought into sharp focus at a meeting for discussion of insurance problems, held in advance of the National Conference on Medical Service last month in Chicago.

There were reports from four medical society plans all launched in accordance with principles laid down by the AMA's House of Delegates for such plans.

All are independent of, but have affiliations with, hospital service plans. All offer a surgical plan as well as a medical and surgical coverage and, for the most part, subscribers are sought through employed groups with premiums deducted by the employer from pay checks.

Many figures were presented about these undertakings but they mean little, as yet, because experience and the number of subscribers to date do not warrant any useful conclusions.

The difficulties inherent in any prepayment plan for medical services have been pointed out frequently in these columns. The existence of these difficulties does not, of course, preclude the possibility that experience and further investigation will some day produce a workable formula.

It seemed to Minnesota representatives who attended this discussion meeting that the formula had not yet been found, or at least that no formula so far used had yet proved its practicability.

Still The Old Hurdles

The society which undertakes to start such a plan still has the old hurdles to face—how to protect it from chisellers; how to make it cheap enough to sell and remunerative enough to guarantee good service; how to operate legally as a non-profit organization within the existing insurance laws of the state; how to secure accurate figures and paper work within the limits of time and inclination of busy participating doctors, et cetera.

The spirit of pioneering among medical or-

ganizations is undoubtedly praiseworthy and the four pioneers who presented their experiences to date in Chicago are providing information which may be invaluable to others in time to come.

Education Important, Too

But it should be remembered also that there are many kinds of pioneering open to physicians' organizations. One of them involves a really active and effective leadership in public health education, a field of at least equal value to the ultimate welfare of the private practice of medicine in the United States. In this field, also, new patterns are being made but the dangers, uncertainties and disagreements inevitably attendant upon social experiments such as health insurance do not intrude themselves. Minnesota, though vastly interested in the success or failure of the pioneers in Michigan, New York and Western New York and California, has been content for the present to pioneer in the field of health education. For the present its committee on sickness insurance and its Council are both of the opinion that neither the people of Minnesota nor the doctors will suffer by the conservatism of this course.

Michigan's Report

Michigan's plan has been frequently described in these columns. Latest figures as reported in Chicago showed 2,117,927 member-months of service for its Surgical Group plan (offering in addition to hospitalization, payment of surgeon's fees while hospitalized) in 1941. For its complete medical service (including medical and surgical care) the figure was 74,726 member-months of care. On the basis of comparisons with the United States Public Health Service surveys of 1928-31, Michigan figures show that subscribers to their medical and surgical service received 3.25 times as much surgical care as persons in the general public. The fact, however, that their figures include many people who sub-

scribe only for hospital service makes this high ratio somewhat less impressive.

Elaborate diagnostic codes and schedules of benefits were distributed at the Chicago meeting. Financial reports weigh heavily in the red but are not necessarily significant of the ultimate success of the project. The Michigan State Medical Society generously underwrote the plan in its inception but only time will tell whether the venture can make ends meet.

Medical Expense Insurance

There are two plans in operation under medical society sponsorship at the present time in New York. One is in Brooklyn and New York City, the other in western New York. The first, also, is familiar to all students of health insurance though it is only now beginning to solicit subscribers. It is New York's Medical Expense Insurance, an indemnity rather than a service type of insurance. For certain premiums, graduated according to the income of the subscriber, certain definite sums are paid up to a maximum of \$300 in a year. The fee schedule used in Workmen's Compensation cases in New York is to be used by the doctor in charging fees to subscribers up to incomes of \$175 a month. Beyond that it is not intended that payments shall provide in all instances for the complete cost of medical care. Such subscribers shall pay any other amount agreed upon directly by the doctor. This is a plan of considerable complication, with its graduated rates for various income groups. Its success in operation will be closely watched.

"Blue Shield"

The "Blue Shield" plan of Western New York offers, in coöperation with the "Blue Cross" hospitalization plan, a contract for surgical care alone, or for medical and surgical care with restrictions on maternity care, or complete medical, surgical and maternity care with restriction.

Benefits of the plan are restricted to families with incomes of \$3,000 or under, for individuals of \$1,800 or under, for man and wife of \$2,500 or under. Maximum cost for all benefits for a family of four, including hospitalization, would be \$57.60 a year.

California Plan

The story of health insurance under medical

society sponsorship has been checkered and marked with disappointments in California. As reorganized at present under sound management, the plan offers medical, surgical and hospital service at a lower premium than anywhere else in the country with an income limit for families of \$3,000 for eligibility to medical and surgical services. Hospital services are open to all. As in the Michigan plans and in the New York Medical Expense Insurance, the subscriber pays for the initial two visits in each ailment. The Blue Shield plan of Western New York omits this customary safeguard. Hospital service, only, is available to families of subscribers in California. Total cost for a female subscriber (more than for males) is \$26.60 a year.

ARMY PROBLEMS FIRST

Personnel problems for the armed forces and for civilian defense naturally occupied a considerable portion of the program time in the 1942 National Conference on Medical Service held in Chicago, Sunday, February 15.

In view of the fact that this conference originated in Minnesota and was held here annually for many years, Minnesota representatives take an especially active interest in its deliberations. Many officials of the state medical association attend and this year the president of Minnesota's Council, Dr. W. L. Burnap, of Fergus Falls, was elected secretary of the conference for next year.

His official duties will be concerned with meeting arrangements and program, acting with Dr. J. D. McCarthy of Omaha, who is next year's president. Dr. McCarthy acted as secretary this year.

Any differences organized medicine may have had with Washington are now submerged in a common effort to promote the national defense and the strengthening of the armed forces.

Increasing the Check-off

One Washington tendency was noted, however, and delegates cautioned to act in consequence. There is a definite effort in the Social Security department to put compulsory sickness insurance into the law, at least for industrial employees. It has been mentioned as a desirable addition to Society Security aids by the President himself, and will undoubtedly appear in some

form in all legislation proposed by the department. Any addition to present Social Security aids will increase the salary check-off of workers by a considerable sum and should be opposed on those grounds as well as on the ground that compulsory sickness insurance is unnecessary and unwise for American workers.

There may be no great interest in any such plan in Congress at the present time; but the general tendency is to pass quickly whatever seems necessary for successful prosecution of the war and without too careful investigation. Congressmen and senators should be informed when such legislation is proposed of the danger of increasing Social Security expenditures for such a purpose.

HOW MANY DOCTORS?

Figures from Col. George F. Lull, chief of the personnel division of the United States Army Medical Corps:

- The army will need a total of 23,658 physicians to fill its needs this year.
- There are only 11,790 physicians in the service now.
- A total of 13,000 more will be needed by the end of 1942.
- There are approximately 3,600 officers of the Medical Reserve Corps who have not yet been called.
- Of these, 1,500 are interns and 1,700 have been deferred because they are essential in civilian positions.
- Also 104 of them are colonels and lieutenant colonels who cannot be placed at the present time because their grades are not open.
- That leaves only 296 reserve officers who are available in the reserve at the present time.

At the Chicago meeting Col. Lull urged all physicians in civilian life who can be spared to enter the service immediately. He estimated that there are some 50,000 in the age group from twenty-seven to thirty-six, of whom 30,000 would be physically qualified for active duty.

Obviously army needs are great but physicians should not forget that civilian needs are also important and that in some sections they are acutely threatened.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

Glencoe Physician's License Suspended for Five Years

Re: revocation of license of Arthur H. Langhoff, M.D.

On February 13, 1942, the Minnesota State Board of Medical Examiners suspended for a period of five years the license to practice medicine formerly held by Arthur Harry Langhoff, M.D., Glencoe, Minnesota. Dr. Langhoff was charged with purchasing, dispensing and administering "grossly excessive amounts" of various derivatives of opium. The joint investigation conducted by the Federal Bureau of Narcotics and the Minnesota State Board of Medical Examiners disclosed that in a period of twelve months, between December 7, 1940, and December 6, 1941, Dr. Langhoff purchased in the excess of 35,000 narcotic drug tablets made up chiefly of morphine sulphate and dilaudid. During the same period of time Dr. Langhoff issued in excess of 400 prescriptions for various derivatives of opium. During the same period of time Dr. Langhoff failed to keep adequate dispensing records. Dr. Langhoff admitted the truth of the charges against him.

Dr. Langhoff is fifty-one years of age and was born at Mountain Lake, Minnesota. He graduated from the Medical School of the University of Minnesota in 1921. Dr. Langhoff has practiced at Glencoe, Minnesota, for the past twenty years.

NEW AGENCY TO HELP RATION NATION'S DOCTORS

PAS (officially the Procurement and Assignment Service under the Office of Defense Health and Welfare Services) has just been given the job of helping the Selective Service System ration the nation's supply of medical doctors, dentists and doctors of veterinary medicine.

"Since war was declared, the shortage of these professional men has become acute," Brig. Gen. Lewis B. Hershey, director of Selective Service, points out in a memorandum to state directors (*Journal, American Medical Association*, Feb. 7).

Each of them, consequently, must serve "where he can render the greatest professional service to the nation."

Local Selective Service boards when classifying doctors, dentists and veterinary doctors are therefore expected to consult PAS committees of the corps areas on the availability of such professional men in the community. The authority of the Selective Service System to classify registrants is not affected but the information from PAS will help in making the "most effective allocation of medical manpower."—*Science News Letter*, February 14, 1942.

WORKMEN'S COMPENSATION LAW IN MINNESOTA

SINCE its passage, the dermatologist has looked upon the Workmen's Compensation Law in Minnesota with a bilious eye. Only a very few cases coming under our observation are covered by the law.

A workman with a contact dermatitis caused by anything in his work should get the same compensation as one that has suffered an injury. In fact, a contact dermatitis usually connotes an increased sensitivity to the offending substance and frequently the man is unable to continue in his work, so loses his job or has to be transferred to other work where he does not come in contact with the offending substance.

Contact or occupational dermatitis can be caused by an endless number of substances; some of which are primary irritants and cause an immediate irritation and some only after working in them for weeks and months.

Cases Never Covered

In the Minnesota law, we dermatologists almost never get a case that is covered by the law. Included in the law are the following substances that might cause a dermatological condition: lead, mercury or phosphorus poisoning or their sequelae, arsenic, wood alcohol, nitro and amido derivatives of benzene, carbon bisulphide, nitrous fumes, nickel carbonyl, tetrachloromethane or any substance used as a solvent for acetate of cellulose, African boxwood, chrome ulceration, cancer or ulceration of the skin due to tar, pitch, bitumen, mineral oil in paraffin or any compound, product, residue of any of these substances.

A glance at the above enumerated substances will show that they do not include any of the more common causative factors of contact or occupational dermatitis.

New Legislation Needed

What should be done about this? In order to properly protect the workmen in Minnesota from any and all injuries of the skin and dermatitis we

should have compensation laws similar to those of Massachusetts, New York, Wisconsin and possibly a few other states. Anything that causes an occupational dermatitis should be included in the law. Labor in this state has long been interested in such a law and hearings have been held in Saint Paul on this subject but nothing came of them. Further efforts should be made to protect the workmen of Minnesota and to include all cases of industrial dermatitis in the compensation law.

S. E. SWEITZER, M.D.

MUST KEEP PACE

The principal public health problem today is presented by large industrial plants, Surgeon General Thomas Parran said recently in Chicago.

Industrial hygiene services must keep pace with the needs arising from high speed assembly lines he said.

Government statisticians have arrived at the enormous figure of 15,000,000 for the number of men and women employed in industry this year.

In Great Britain they have found it necessary to have one physician, at least, in each large plant together with assistants. In our own plants, on the other hand, less than one-seventh of our industrial employes have such plant service.

Dr. Parran urged that everything possible be done for protection of civilian health in the emergency. The most serious problem centers around military camps, industrial plants and shipyards located in small towns which have developed over night into large cities and where there is almost universally insufficient medical personnel.

The U. S. Public Health Service is short about 1,000 for these and other services. They have, however, developed teams of physicians and engineers who are sent out in emergencies.

Increase in venereal disease is one of the serious problems connected with the development of camps and defense industry centers. In one area in particular, the number of prostitutes leaped from 100 to 5,000. Gonorrhea in the army has increased from 27.7 to 40.3 per thousand men, largely as a result of commercialized vice in military and industrial areas. The federal government has the power to clean up these conditions now, if local officials do not do it.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of December 10, 1941

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 10, 1941. Dinner was served at 7 o'clock and the meeting was called to order at 8 o'clock by the president, Dr. John M. Armstrong.

There were forty-six members and one guest present. Minutes of the November meeting were read and approved.

The annual election of officers was held and the following elected to serve for the year 1942:

President.....Martin Nordland, Minneapolis
Vice President....H. B. Zimmermann, Saint Paul
Secretary-Treasurer....E. V. Kenefick (re-elected)

The President said the Executive Committee wished to present the name of Dr. Owen Parker, of Ely, Minnesota, as an Honorary Member of the Academy, to be transferred from the Associate Member list, Dr. Parker having retired from practice on account of ill health. Motion made, seconded and carried.

The scientific program followed.

THE PROBLEM OF BLEEDING FROM ESOPHAGEAL VARICES

A. M. SNELL, M.D.

Dr. Snell, of Rochester, reported a case and necropsy findings. Lantern slides were shown.

Discussion

DR. J. M. ARMSTRONG, Saint Paul: I would like to ask Dr. Snell how long this surgical procedure has been tried out.

DR. SNELL: The first direct injections of esophageal varices were done at the Clinic by Dr. H. J. Moersch about two years ago. The original work was done by Crafoord and Freckner, of Stockholm.

DR. ARMSTRONG: The reason I asked was that I had a patient with this trouble about nine years ago; the pa-

tient lived three days, and he did have a very large liver.

DR. SNELL: I still think that ligation of the coronary veins may under the circumstances be a life-saving procedure. In this case it certainly produced very good temporary results.

DR. ARMSTRONG: Was she unconscious when she came in?

DR. SNELL: Practically so. In spite of this fact, the surgical procedure was very well tolerated.

ADRENO-GENITAL SYNDROME DUE TO ADRENO-CORTICAL TUMOR

MAX HOFFMAN, M.D., and F. E. B. FOLEY, M.D.

Drs. Max Hoffman and Frederic E. B. Foley, Saint Paul, briefly described the adreno-genital syndrome due to adreno-cortical tumor and reported a case of cortico-adrenal tumor in the female with extensive masculinizing changes, in which repeated assays of androgen and estrogen excretion in the urine were made before and after operation. Radiographs, outlining the adrenal tumor by perirenal air injection, were shown. Successful surgical removal of the tumor was described and illustrated by drawings and a motion picture film. Before and after photographs of the patient demonstrating rapid and remarkable disappearance of the masculine features were shown and the patient, a woman aged twenty-four, was exhibited. The presentation was discussed by Drs. J. M. Armstrong, A. M. Snell, M. B. Visscher, and E. A. Regnier.

A paper on the subject presented, case report and discussion will be offered for publication in a subsequent issue of MINNESOTA MEDICINE.

The meeting adjourned.

E. V. KENEFICK, *Secretary*.

Meeting of January 14, 1942

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 14, 1942. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the president, Dr. Martin Nordland.

There were forty-nine members and four visitors present.

Minutes of the December meeting were read and approved.

Dr. Nordland expressed his sincere appreciation of the honor given him in electing him president of the Academy.

There was a short discussion on the question of dues of the men called into service, and a motion was carried that any member of the Academy in service be continued on the Active membership list and his dues remitted for the period of such service.

The secretary read a letter from Dr. Donald McCarthy, a candidate for election, stating that he had been called into active service and would be unable therefore to prepare his thesis in the required time for presentation. A motion was carried that Dr. McCarthy be admitted to membership without the thesis requirement.

Dr. Frank Corbett's name was transferred from the Active to the Honorary membership list, following his request for transfer to Senior list.

Dr. John M. Armstrong, Saint Paul, then read his address as retiring president, the title being "Asiatic Cholera in Saint Paul." Lantern slides were shown of early Saint Paul physicians, some of the city of Saint Paul in the 1850's and '60's, and also of death records made in which those due to cholera were listed.

The meeting adjourned.

E. V. KENEFICK, M.D., *Secretary*.

MEDICAL BROADCAST FOR MARCH

The Minnesota State Medical Association broadcasts weekly at 10:45 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth. Speaker: William A. O'Brien, M.D., Director of Postgraduate Medical Education, Medical School, University of Minnesota.

March 7—Energy Needs and Requirements
 March 14—Diet in Pregnancy and Lactation
 March 21—Diet in Infancy and Childhood
 March 28—Nutrition and the Teeth

POSTGRADUATE COURSES

Among postgraduate courses announced by the Advisory Committee on Postgraduate Courses of the American College of Physicians are three to be given in Minnesota.

A course in Peripheral Vascular Diseases, Including Hypertension, will be given by the Mayo Foundation of the University of Minnesota and the Mayo Clinic at Rochester, April 6-18, with Dr. Edgar V. Allen as director.

Another course in Arthritis and Rheumatic Diseases will also be given in Rochester, April 13-18, with Dr. Philip S. Hench as director.

During the period, April 6-18, a course on Internal Medicine will be presented at the University of Minnesota Center for Continuation Study in Minneapolis. Directors are Julius M. Nolte, Dr. William A. O'Brien and Dr. Cecil J. Watson.

MINNESOTA PATHOLOGICAL SOCIETY

Dr. C. J. Watson, professor of medicine at the University of Minnesota Medical School, will address the meeting of the Minnesota Pathological Society, March 17, on the subject: "Recent Studies of the Degradation Products of Hemoglobin."

HEART PROGRAM FOR CHILDREN

Mr. Walter W. Finke, Director of the Division of Social Welfare, State of Minnesota, announces that a heart program for children under the age of twenty-one years has been approved by the Children's Bureau, Washington, D. C., and is now ready to be set in operation.

This program is to be a function of the Bureau for Crippled Children of the Division of Social Welfare. Special emphasis will be placed on children with rheumatic heart disease who are in need of convalescent care.

Because of limited funds, only patients from rural Hennepin, rural Ramsey, Carver, Scott, McLeod, and Dakota Counties will be accepted for care. Children needing convalescent care or acute cases needing hospital care will be hospitalized at the Children's Hos-

pital in Saint Paul, where special provision has been made for these cases. A weekly out-patient clinic will be held on Friday mornings at Children's Hospital.

Dr. Malvin J. Nydahl, Head of the Bureau for Crippled Children, is pleased to announce that Dr. Paul Dwan, pediatrician, who has had a great deal of experience in rheumatic heart disease, will perform the clinical work of the heart program.

Applications for this care should be made to the Bureau for Crippled Children, Division of Social Welfare, Globe Building, Saint Paul, Minnesota. Any physician wishing to refer a patient for this needed care can do so by writing to the above address.

REDWOOD-BROWN COUNTY MEDICAL SOCIETY

Dr. O. H. McPheeters of Minneapolis read a paper on "The Injection Treatment of Varicose Veins" at the quarterly meeting of the Redwood-Brown County Medical Society in New Ulm, January 29.

Forty-five physicians and their wives attended the dinner at Turner Hall which preceded the medical meeting. The auxiliary was entertained at the home of Dr. and Mrs. Theodore F. Hammermeister.

WASHINGTON COUNTY MEDICAL SOCIETY

The regular monthly meeting of the Washington County Medical Society was held Tuesday, February 10. The scientific program was supplied by complete sound and full color film on "Varicose Veins and Their Complications," by Becton-Dickinson and Company, presented by Richard N. Shaw of the Hospital Service Department. The film is one approved by the American College of Surgeons.

The vaccination and toxoid program is meeting with favorable responses, and the work will soon be under way.

Washington County was reported to be almost free of syphilis, with only one positive reactor in about 425 men examined for the army.

E. SYDNEY BOLEYN, M.D., *Secretary*.

FREEBORN COUNTY MEDICAL SOCIETY

At the January meeting of the Freeborn County Medical Society, Dr. A. Gullixson, presiding, many matters of importance both to the society and to the residents of Freeborn County, came up for discussion.

Dr. L. J. Kassa gave a very interesting report on the tuberculin testing of school children, a task to which he has devoted much of his time. His report included a comparative study of the status of tuberculosis in Freeborn County as compared to other counties. A resolution followed to the effect that the County Superintendent of Schools and those in charge

You Will Want to Know About the Kenny Method

for the

Treatment of Infantile Paralysis in the Acute Stage

by Sister Elizabeth Kenny of Australia

The success of Sister Kenny's method of treating infantile paralysis attracted the attention of medical men throughout the world. Her work in the past two years, at the University of Minnesota and the General Hospital in Minneapolis, has demonstrated to the satisfaction of many prominent physicians that her treatment definitely produces remarkable results.

Her revolutionary methods, first evolved on the Australian frontier and later demonstrated in Melbourne, challenged the attention of leading international polio-

myelitis authorities who encouraged her to come to the United States to continue her work.

This book, containing her lectures, is the only text book on the subject of her methods. It reveals, for the first time, the history of the development of her treatment and its complete explanation **written by Sister Kenny, the originator of this method.** Completely illustrated and with full detail, it brings to the medical profession a highly informative and educational study.

Price \$3.50 postpaid. You may order by check or C. O. D., either from the publisher or from your book dealer.

ANNOUNCES CONTINUOUS COURSES

SURGERY—Two Weeks' Intensive Course in Surgical Technique with practice on living tissue, every two weeks throughout the year. General Courses One, Two, Three and Six Months; Clinical Courses; Special Courses. Rectal Surgery every week.

MEDICINE—Two Weeks' Intensive Course will be offered starting June 1st. Two Weeks' Course in Gastro-Enterology will be offered starting June 15th. One Month Course in Electrocardiography and Heart Disease every month, except December and August.

FRACTURES AND TRAUMATIC SURGERY—Two Weeks' Intensive Course will be offered starting May 4th. Informal Course available every week.

GYNECOLOGY—Two Weeks' Intensive Course will be offered starting April 6th. Clinical and Diagnostic Courses every week.

OBSTETRICS—Two Weeks' Intensive Course will be offered starting April 20th. Informal Course every week.

OTOLARYNGOLOGY—Two Weeks' Intensive Course will be offered starting April 6th. Clinical and Special Courses starting every week.

OPHTHALMOLOGY—Two Weeks' Intensive Course will be offered starting April 20th. Five Weeks' Course in Refraction Methods starting May 11th. Informal Course every week.

ROENTGENOLOGY—Courses in X-Ray Interpretation, Fluoroscopy, Deep X-Ray Therapy every week.

General, Intensive and Special Courses in All Branches of Medicine, Surgery and the Specialties.

**TEACHING FACULTY—ATTENDING
STAFF OF COOK COUNTY HOSPITAL**

Address: Registrar, 427 S. Honore St., Chicago, Ill.

(Continued from Page 224)

of schools in smaller towns require all school teachers to have a Mantoux test and to be x-rayed in an attempt to eradicate any possible carriers of tuberculosis.

In an effort to immunize the greatest possible number of school children to smallpox and diphtheria, it was decided that group immunization be instituted at the schools, on a definite date, to be arranged by the school authorities, the county nurse and the doctors.

Dr. F. G. Folken presented a comparative report on the expenditure for medical relief care in Freeborn County with that of neighboring counties. His report brought out the fact that the expenditure in Freeborn County was considerably less than that of the other counties. To unify medical fees throughout the state a fee schedule as submitted by the state organization on medical relief care will be carried out in the future.

The president appointed Drs. P. M. Gamble and L. Donovan as a committee to investigate the probable reasons for the present shortage of nurses.

After the treasurer's report it was voted to purchase defense bonds with surplus funds.

The following were elected as officers of the Freeborn County Medical Society for the coming year: President, Dr. F. W. Calhoun; vice president, Dr. R. R. Swanson; secretary, Dr. E. S. Palmerton; treasurer, Dr. L. Donovan. Drs. W. P. Freligh, M. O. Nesheim and J. P. Person were elected to serve three, two and one years respectively as censors, and Dr. J. W. Gamble was elected as delegate to the State Medical Convention with Dr. L. Prins as alternate.

L. PRINS, *Secretary.*

MINNESOTA SOCIETY FOR THE CONTROL OF CANCER

The annual meeting of the Minnesota Society for the Control of Cancer was held February 24 at Coffman Memorial Union on the University of Minnesota campus.

The afternoon program included the showing of the sound movie, "Choose to Live," which depicted one woman's victorious encounter with cancer; and an address, "A Call to Service," by Mrs. David S. Long of Harrisonville, Missouri, regional commander of the Women's Field Army of the American Society for the Control of Cancer.

Guest speaker at the dinner which followed the afternoon session was Dr. W. D. Stovall, director of the State Laboratory of Hygiene and clinical pathologist at the University of Wisconsin. He spoke on "Cancer—Its Prevention and Control."

Dr. William A. O'Brien, director of postgraduate medicine at the University of Minnesota, was reelected president of the society. Other officers elected are Dr. M. W. Alberts, Saint Paul, first vice president; Mrs. E. W. Miller of St. Peter, second vice president; Mrs. W. B. Roberts, Minneapolis, secretary; and Louis W. Hill, Jr., Saint Paul, treasurer.

In Memoriam

Eric Olonzo Giere

Dr. E. O. Giere, a surgeon for the past fourteen years in Minneapolis, although he continued to live in Saint Paul, was taken ill on the night of December 31, 1941, and died in Fairview Hospital, February 12, 1942. Dr. Giere was seventy-three years of age and had completed fifty years of practice to the day.

Dr. Giere was born in Deerfield, Wisconsin, April 10, 1868. He received his preliminary education at Luther College, Decorah, Iowa, and at Saint Olaf's College, Northfield, Minnesota. His medical degree was obtained from the University of Minnesota Medical School in 1892.

After a three months' internship at the State Hospital in Rochester, Dr. Giere began practice at Hayfield, Minnesota, in 1893. In 1895 he moved to Madison and in 1915 to Watertown, South Dakota. From 1921 until 1927 he practiced in Saint Paul, when he moved his office to Minneapolis.

At one time Dr. Giere attended clinics in Oslo, Copenhagen, Berlin and London. He took a number of postgraduate courses in New York, Chicago and New Orleans on various occasions to perfect himself in his chosen specialty of surgery. He established a clinic in Watertown and in 1927 established, with his three sons, the Giere Clinic in Minneapolis. At one time he was Chief of Staff of the Fairview Hospital.

Dr. Giere has been a member of the American College of Surgeons since its founding in 1914. He was a member of the Hennepin County Medical Society, the Minnesota State Medical and American Medical Associations.

Dr. Giere is survived by his wife; four daughters, Mrs. Olaf Larson and Mrs. Leonard Johnson of Montevideo, Minnesota, Mrs. Rodli Erling of Minneapolis and Mrs. Potter Aldrich of Saint Paul; and four sons, Rev. Verne Giere of Edgerton, Wisconsin, Dr. R. W. and Dr. J. C. Giere of Minneapolis, and Dr. Carl Norman Giere, at present a captain in the army.

DR. EVANS TO SPEAK AT UNIVERSITY

Dr. Herbert McLean Evans, director of the Institute of Experimental Biology at the University of California, will deliver a lecture on "Recent Results from Study of the Anterior Pituitary" in the Medical Science Amphitheater of the University of Minnesota, Wednesday, April 1, at 8 p.m. This lecture is under the joint auspices of the University of Minnesota Medical School and the Society of the Sigma Xi, and is open to all interested.

Internationally distinguished for his discovery of Vitamin E and his studies of the Growth Hormone secreted by the anterior lobe of the pituitary gland, Dr. Evans will speak from a background of almost twenty years' research on the subject chosen for his lecture. He will discuss the pituitary body as a regulating center for the activities of the other endocrine glands and as a participant in the regulation of body metabolism. In summarizing securely won results on this rapidly advancing frontier of science, few, indeed, are as qualified as Dr. Evans to separate fact from fancy.

WOMAN'S AUXILIARY

MRS. JOHN J. RYAN, *President*
Saint Paul, Minnesota
MRS. L. R. BOIES, *Publicity Chairman*
Knollwood, Hopkins, Minnesota

COUNTY NEWS

Washington

At a luncheon held Tuesday, February 10, at the home of Dr. and Mrs. Strand, Bayport, Minnesota, it was the pleasure of the Washington County Auxiliary to have as its guest and speaker, Mrs. John J. Ryan, Saint Paul, State Auxiliary president.

Clay-Becker

Recently elected officers for Clay-Becker Auxiliary include: president, Mrs. C. W. Moberg, Detroit Lakes; vice president, Mrs. F. D. Thysell, Hawley; secretary-treasurer, Mrs. S. B. Seipz, Barnesville. A great deal of credit is due the group in the splendid result netted from the sale of articles made at Sand Beach Sanatorium, Lake Park, Minnesota. The combined total of the sale first held in Detroit Lakes and later in Barnesville, was \$93.32.

Ramsey

The Auxiliary Red Cross unit organized in October with Mrs. Harvey Beek in charge assisted by Mrs. John Madden, is doing fine work. It is meeting at the House of Hope Church, Saint Paul, on Monday and Thursday from 10:00 a.m. to 3:00 p.m., and on Wednesday evenings from 7:00 to 9:00 p.m. Besides making surgical dressings and bandages, the unit is also doing sewing and knitting. Mrs. Beek, who is a member of the Ramsey County Red Cross Board, is in charge of all surgical dressings made at the House of Hope Church by other Red Cross units meeting there.

Hennepin

Mrs. F. S. McKinney presided at the meeting of the Auxiliary held Friday, February 6, at the Medical Arts Lounge. Interesting movies of Norway, Sweden, Denmark, and England taken during their trip abroad just before the war broke out in Europe, were shown by Mrs. Malcom Hanson, a member of the Auxiliary.

Dr. C. C. Kennedy, Minneapolis, vice chairman of the State Medical and Surgical Relief Committee of America, gave a brief history of the organization and its aims. Two doctors in New York started the group two years ago and at their call for help in this work, sixty men responded from the United States at large. The organization has steadily grown, and today instead of sending the medical and surgical supplies collected to England, these articles are being used for United States war efforts. A request for such supplies recently came from Queen's Hospital in Honolulu. A committee of Auxiliary women under the direction of Mrs. F. S. McKinney has just finished a collection campaign of these medical and surgical supplies for

the organization in downtown medical offices of Minneapolis. Dr. Kennedy heartily thanked the women for their concentrated efforts which netted baskets and baskets of supplies—as he said, “Literally one and one-half tons!” Incidentally, this same committee of women hopes in the near future to canvass the medical offices in the outlying districts of the city. Dr. O. W. Wangenstein, Minneapolis, is state chairman of the Medical and Surgical Relief Committee of America.

After the program of the afternoon, tea was served under the direction of Mrs. Ernest Meland assisted by Mmes. Robert Karon and Johannes Moen. Mmes. Frank Bryant and C. N. Spratt acted as hostesses.

Nicollet-Le Sueur

The Auxiliary held a dinner meeting at the Nicolle Hotel in St. Peter, Minn., Wednesday, February 11. A business meeting preceded the evening's program.

Rice

Rice County Auxiliary reports that meetings are held the fourth Tuesday of each month at the home of one of its members. The attendance ranges from fourteen to eighteen members and the program for the year thus far has included a nutrition talk and one on Public Health and its achievements. Special projects engaged in are knitting and sewing for the Red Cross.

STATE AND NATIONAL NEWS

State Board Meetings

The State Board Meeting of the Auxiliary will be held in Minneapolis about the middle of March. This will be shortly before Easter and it is hoped a large number of women from the state will be able to attend.

National Meeting

Haddon Hall will be the headquarters for the annual meeting of the Woman's Auxiliary to the American Medical Association, which will be held in Atlantic City, New Jersey, June 8-12, 1942. Requests for reservations should be sent immediately to Haddon Hall, Atlantic City, New Jersey.

Deepest sympathy of the State Auxiliary is extended to Mrs. W. W. Moir, Minneapolis, Minnesota, in the loss of her husband, Dr. W. W. Moir.

An x-ray of Gainsborough's famous painting “Blue Boy” at the Henry E. Huntingdon Art Library, San Marino, Calif., revealed the lower half of a man's head, front face; the artist apparently began another portrait, then quit.

If every driver would reduce his average speed by 10 miles an hour he would get about 6,300 extra miles out of his tires, according to a major rubber company.

ORALLY OR BY INJECTION

Metrazol Tablets, Oral Solution and Powder for prescription compounding.

COUNCIL ACCEPTED

For circulatory and respiratory support in the emergencies of congestive heart failure or pneumonia prescribe Metrazol, tablets or in solution, three or four times a day. In extreme cases oral administration may be supplemented by injections.

DOSE: $1\frac{1}{2}$ to $4\frac{1}{2}$ grains (1 to 3 tablets, or 1 to 3 cc. oral or parenteral solution).

OF GENERAL INTEREST

Dr. Theodore J. Keskey has been named school physician for the Mountain Iron school.

* * *

Dr. George F. Brooks of Stillwater has given up his offices for the time being on account of poor health.

* * *

Dr. and Mrs. D. Kalinoff of Stillwater left January 28 for Biloxi, Miss., where they will spend the rest of the winter.

* * *

Dr. H. T. Sherman, who has been practicing in Nerstrand, has moved to Kasson where he has opened offices.

* * *

Dr. Otis S. Marsh of Minneapolis has become associated with Dr. W. E. Macklin of Litchfield in the practice of medicine.

* * *

Dr. M. P. Virnig of Wells served as chairman of the Faribault County committee for the celebration of the President's Birthday.

* * *

Dr. Roscoe E. Conklin, a resident in medicine at Minneapolis General Hospital, is with the diabetic hospital service of the Mayo Foundation, Rochester.

* * *

Dr. Willard L. Burnap of Fergus Falls was elected secretary of the National Conference on Medical Service, held in Chicago, February 15.

* * *

Dr. Lillian L. Nye, Saint Paul, has received her life membership certificate in the American College of Physicians, dated October 15, 1941.

* * *

Dr. Wayne S. Hagen of Minneapolis is Chief of the Medical Service of the United States Army Station Hospital at Fort Hamilton, New York.

* * *

Dr. Chester Clark, who has been located at Browns Valley for the past year, has closed his office there and has moved to Cottonwood where he will continue his practice.

* * *

Dr. O. K. Behr, who has been at Minneapolis General Hospital taking advanced work in urology, has resumed his practice with the Crookston Clinic in Crookston.

* * *

At a recent meeting of the staff physicians of Itasca Hospital in Grand Rapids, Dr. F. M. Jolin of the Jolin, Jolin & McKenna Clinic, Bovey-Grand Rapids, was named chief of staff.

* * *

Dr. O. B. Fesenmaier, who has offices in New Ulm, has established a part-time office in Hanska. He will continue to maintain his practice in New Ulm where he has been located since 1937.

Dr. Leo G. Rigler, head of the radiology department at the University of Minnesota Medical School gave the Carman lecture before the St. Louis Medical Society in St. Louis, Missouri, February 24.

* * *

Dr. Thomas J. Edwards of Saint Paul, formerly with offices in the Hamm building, opened new offices March 1 at 330 Lowry Medical Arts Building. His practice is limited to medical and surgical care of the eyes.

* * *

Orders for Drs. Morris E. Freedland of Minneapolis and Dr. Lester E. Frogner of Grand Marais, both first lieutenants, to report for active duty with the United States Army Medical Corps have been revoked.

* * *

Dr. Clarence M. Larson has been named chief of staff at Swedish Hospital in Minneapolis. Dr. Elmer F. Lundquist was elected vice president; Dr. Charles R. Drake, treasurer; and Dr. Roy A. Lundblad, secretary.

* * *

Dr. John L. McKelvey, head of the department of obstetrics and gynecology at the University of Minnesota Medical School, will be a guest speaker at the meeting of the Iowa State Medical Society in Des Moines, April 16.

* * *

Dr. Raymond D. Manchester, who has been located in Park Rapids, left Minnesota, February 15, for Los Angeles to continue his practice of medicine. Dr. and Mrs. Manchester visited relatives in Minneapolis for two weeks before going to California.

* * *

Dr. H. G. Rice of Moorhead was elected president of the Medical staff of St. Ansgar Hospital in Moorhead at the recent annual meeting. Dr. S. B. Seitz of Barnesville was named vice president, and Dr. V. D. Thysell, Hawley, secretary-treasurer.

* * *

Among speakers at the fifty-seventh annual session of the Mid-South Post Graduate Medical Assembly held in Memphis, Tennessee, February 10-13, was Dr. John de J. Pemberton of Rochester whose topic was "Malignant Lesions of the Colon and Rectum."

* * *

Appointment of Ruth E. Grout, Ph.D., as assistant professor of preventive medicine and public health at the University of Minnesota, is announced. Dr. Grout, who has been engaged in health education work with the TVA, will join the staff next fall.

* * *

The marriage of Dr. Joseph E. Murphy of Marshall and Miss Aida B. Fedrizzi of Coleraine took place February 7 in Coleraine. Dr. and Mrs. Murphy are at home in Marshall where Dr. Murphy is associated with Dr. W. W. Yaeger in the practice of medicine.

Re-elected chief of staff of Eitel Hospital in Minneapolis at the annual meeting was Dr. Gilbert J. Thomas. Dr. Charles Hallberg was named assistant chief and Dr. Alton Olson, secretary. Dr. F. E. Harrington spoke on the responsibility of the hospital staff in civilian defense.

* * *

Dr. Gilbert Thomas of Minneapolis was in Chicago, February 13, 14 and 15, for the examinations of the American Board of Urology, of which he is secretary. He also attended the meeting of the Council on Medical Education and Hospitals of the American Medical Association, February 16, and a meeting of the advisory board of medical specialties.

* * *

The Foundation Prize, consisting of a cash award of \$150, is offered this year by the American Association of Obstetricians, Gynecologists and Abdominal Surgeons. Those eligible are interns, residents or graduate students, and physicians devoting themselves to this specialty. Those interested may address Dr. James R. Bloss, 418 Eleventh Street, Huntington, West Virginia.

* * *

In January last the Japanese attacked Changsha and occupied the Yale-in-China campus as headquarters. Chinese artillery fire and guerilla warfare to the rear of the Japanese lines forced the Japanese to retreat. As they left the campus they set fire to some of the buildings. Though heavily damaged, the hospital was not a complete loss.

* * *

Twin Citians who attended the meeting of the Travel Club of the Central Association of Obstetricians and Gynecologists in Milwaukee, February 14 and 15, were Dr. John L. McKelvey, head of the department of obstetrics and gynecology at the University of Minnesota Medical School; Dr. Claude J. Ehrenberg of Minneapolis; and Dr. E. C. Hartley of Saint Paul. The Marquette University Medical School was host.

* * *

Major Sam Seeley of Chicago, executive officer of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, visited in Minneapolis February 18 and 19. In his honor an informal luncheon was held on the University of Minnesota campus. He is a graduate of the University of Minnesota Medical School '27.

On the evening of February 19, he gave a Mayo Foundation lecture at Rochester.

* * *

Dr. A. R. MacLean of Rochester, a lieutenant in the naval reserve specialist unit, has been called to active duty. He left February 15 for Great Lakes, Illinois, where he will be stationed at the Great Lakes Naval Training Station.

Dr. James P. O'Keefe of St. Cloud has also been called to active duty as lieutenant (junior grade) in the United States Naval Reserve. He has been resident obstetrician at Norwood Hospital in Birmingham, Alabama.

THE *Myrick* INHALATOR

Operates
on a
new
principle

Delivers warm,
moistened air.
Is safe and easy
to use,
simple and
efficient.

Instead of projecting a jet of hot steam into the patient's face, or enclosing the jet in a hood or cone, the steam from the generator of the inhalator

is passed through an injector which draws into the stream of vapor a predetermined amount of cool air. This cools the steam to an acceptable temperature, at the same time removing excess moisture and automatically returning it to the generator. The patient may be placed in the direct path of the vapor stream and is sure to receive a steady flow of cooled, highly saturated vapor—restful and extremely beneficial.

The use of the *Myrick* Inhalator is in cases of acute rhinitis, rhinosinusitis, pharyngitis, tracheitis, laryngitis, bronchitis, after thyrotomy, laryngectomy and tracheotomy and in any postoperative case where there is indication of developing, or already present, respiratory tract infection.

Container accommodating 1½ gallons of water, electric heating unit, nichrome wire with sensitive thermostatic control, which automatically cuts off the current, steam-and-air injector and adjustable flexible metal inhalator tube, with medicants cup..... **\$38.50**

MINNEAPOLIS

OF GENERAL INTEREST

Among new fellows in the Mayo Foundation at Rochester are:

Dr. Bernard L. Kreilkamp of Princeton, Wisconsin, and Dr. Earl M. Anderson and Dr. Dexter E. Guernsey of Minneapolis, all graduates of the University of Minnesota Medical School and interns at Minneapolis General Hospital from July, 1940, to January, 1942.

Dr. Robert A. Murray of Parkers Prairie, graduate of University of Minnesota Medical School '39. He was intern and resident at San Diego County General Hospital from July, 1939, to July, 1941. Since that time he has been in practice with Dr. A. J. Lewis in Henning, Minnesota.

* * *

Dr. R. M. Rosenwald is the new chief of staff of St. Barnabas Hospital in Minneapolis, succeeding Dr. W. G. Schaefer. Other officers named at the recent annual meeting of the medical staff are: Dr. E. J. Lillehei, vice chairman; Dr. Joseph F. Spano, secretary-treasurer; Dr. William Roberts, executive committee chairman.

Charles Bolles Rogers, president of the board of trustees, spoke on the hospital's educational program for medical staff and interns.

* * *

The General Staff of the United States Army has approved the suggestion of the Surgeon General to commission pre-medical students who have been accepted for admission to medical school and first and second year medical students, as Second Lieutenants in the Medical Administrative Corps in exactly the same

manner as the third and fourth year medical students are now being commissioned.

The Secretary of the Navy has also approved a change in regulations whereby it is now possible for pre-medical students who have been accepted for entrance, and all medical students in Class "A" Medical Colleges, to be appointed in the United States Naval Reserve in Class H-V (P) provided they meet physical and other requirements for such appointments.

* * *

Dr. Fred W. Rankin of Lexington, Kentucky, and formerly of Rochester, has been appointed chief consulting surgeon of the United States Army. Dr. Rankin, president-elect of the American Medical Association, was assistant surgeon at St. Mary's hospital in Rochester from 1916 to 1923. From 1926 to 1933 he was a surgeon at the Mayo Clinic and associate professor of surgery in the University of Minnesota Medical School.

In World War I he was in command of a base hospital in France and was discharged with the rank of major. His new appointment carries the rank of colonel.

Dr. Rankin is the son-in-law of the late Dr. Charles Mayo.

* * *

Dr. W. Randolph Lovelace of Rochester, surgeon in the Mayo Clinic and president-elect of the Aero Medical Association, has been appointed director of research and consultant in surgery for the United States army air force in the office of the air surgeon. He reported

Throughout the United States . . .

Physicians are recommending Diaper Services which display the seal of the National Institute of Diaper Services—Because strict sanitation standards are maintained.

The convenient paper roll **HOLDER** assures you continuous supply of **SOLAREUM** Sheeting

When you use SOLAREUM Sheeting you are taking every precaution against contagion. This is appreciated by patients today, as attested by physicians from coast to coast.

Immaculately white and economical; will not break or tear; makes no crackling noise; is soft, clothlike, and comfortable.

for active duty in Washington, D. C., on February 16.

A major in the medical reserve corps of the army, he will hold that rank in his new position which will be in the office of Colonel D. N. W. Grant, the air surgeon. He will direct all aero-medical research for the army air forces and will consult in surgery.

Dr. Lovelace and Walter W. Finke of Minneapolis, state director of social welfare, were honored at a testimonial dinner in Rochester, February 6, on their recent selection by the United States Chamber of Commerce as two of the ten outstanding young men in the nation in 1941. Scrolls attesting the honor were presented to them by Governor Harold E. Stassen.

* * *

Representatives of the newly established National Proctologic Certification Committee include Dr. Walter A. Fansler of Minneapolis, vice chairman; and Dr. Louis A. Buie of Rochester. Dr. Louis J. Hirschman of Detroit, Michigan, is chairman.

The committee was established under the sponsorship of the Section on Gastro-Enterology and Proctology of the American Medical Association, the Section on Proctology of the Southern Medical Association, the American Proctologic Society and the Mid-West Proctologic Society. The committee will co-operate with the American Board of Surgery in passing on the qualifications of applicants who desire certification in proctology, and will have charge of that portion of the examination of these applicants covering the diseases and surgery of the colon, rectum and anus.

Dr. Harold S. Diehl of Minneapolis, dean of medical sciences at the University of Minnesota, addressed two meetings in Chicago last month. On February 15, he spoke before the sixteenth annual meeting of the National Conference on Medical Service (formerly the Northwest Regional Conference) on the subject, "What the Medical, Dental and Nursing Schools May Do to Hasten the Graduation of Their Respective Students."

On February 16, he addressed the thirty-eighth annual Congress of the Council on Medical Education and Hospitals of the American Medical Association. His subject was "The Role of Medical Schools in the War." Dr. Diehl is a member of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians of the Office of Defense, Health and Welfare Services.

* * *

Selection of commissioned personnel for the First Medical Battalion, Minnesota Defense Force, has been announced by Major General Ellard A. Walsh, state adjutant general.

Recruiting of 236 enlisted men to complete the organization is now under way.

Battalion headquarters will be in Rochester with Dr. Andrew B. Rivers of the Mayo Clinic as commanding officer with the rank of lieutenant colonel in the medical corps.

Locations and commanding officers of the following units were announced as:

Effective, Convenient and Economical

THE effectiveness of Mercurochrome has been demonstrated by twenty years' extensive clinical use.

For the convenience of physicians Mercurochrome is supplied in four forms—Aqueous Solution for the treatment of wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

Mercurochrome, H.M.&D.
(dibrom-oxymercuri-fluorescein-sodium)

is economical because solutions may be dispensed at low cost. Stock solutions keep indefinitely.

Mercurochrome is accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

* * *

A program of instruction in the Kenny method is being arranged as the result of a recent conference in Minneapolis, in which Basil O'Connor, president of the National Foundation for Infantile Paralysis, and Don W. Gudakunst, medical director, consulted with medical authorities at the University of Minnesota and with Miss Elizabeth Kenny and her staff.

Three groups will be afforded training at an early date:

1. Physicians in charge of special programs, such as directors of schools of physiotherapy, orthopedic surgeons and those in charge of contagious disease hospitals.

2. Physiotherapists in charge of either teaching programs or larger organizations.

3. Nurses in contagious disease hospitals or other institutions where there are either teaching programs or larger groups of poliomyelitis patients being treated.

Facilities at the University of Minnesota Medical School are limited, and the number of trainees who can be admitted must depend on the number of patients in early stages of infantile paralysis in Minneapolis hospitals, as it is only early stages that are treated by the Kenny method.

* * *

Dr. Philip F. Eckman was named chief of staff of St. Mary's Hospital in Duluth, succeeding Dr. W. C. Martin, February 5, at the annual meeting. Dr. F. N. Knapp is the chief-elect.

Dr. J. S. Spang was elected secretary; Dr. C. M. Smith, chief of medicine; Dr. E. Z. Shapiro, chief of urology; Dr. A. O. Olson, chief of eye, ear, nose and throat; Dr. F. J. Elias, chief of orthopedics; Dr. E. L. Tuohy, chief of laboratories, and Dr. F. J. Hirschboeck, chief of neurology.

Guest speaker was Dr. M. Fernan-Nunez, professor of pathology at Marquette University Medical School in Milwaukee. His talk, "A Medical Travelogue on Spanish America," was illustrated with colored lantern slides and motion pictures. Dr. Fernan-Nunez predicted that with the return of American soldiers from service in tropical lands and southern encampments, tropical diseases would become a considerable problem of medical practice in northern latitudes.

Dr. W. A. Coventry paid tribute to the late Rev. Fr. C. B. Moulinier, S. J., founder of the Catholic Hospital Association, who died in 1941, and unveiled a picture of the priest. This was followed by a tribute paid to Dr. A. E. Walker, member of the hospital staff

for fifty-one years, and the unveiling of his picture by Dr. W. J. Ryan.

* * *

Staff members of the United States General Hospital Unit No. 26 ordered to Fort Sill, Oklahoma, for a raining period before being sent overseas for duty, are presented here. Several members of the staff are waiting orders to join the unit.

Now in Fort Sill are:

Commanding Officer—Lt. Col. F. V. Kilgore.
Sanitary Officer—Theodore Olson, first lieutenant.
Mess Officer—Robert M. Barr, Major, M. C.
Receiving Officer—Gordon C. MacRae, Major, M. C.
Registrar—Albert Hayes, first lieutenant, M. C.
Assistant Medical Supply Officer—Norman O. Holte, second lieutenant, M. A. C.

Medical Service—Joseph F. Borg, lieutenant colonel; Reuben Erickson, major; Douglas P. Head, major; Philip Hallock, major; Samuel A. Weisman, major; Harvey Beek, major; Theodore J. Bulinski, captain; William H. Hollinshead, captain; Robert E. Johnson, captain; Russell C. Lindgren, captain; Stanley W. Lundblad, captain; Lawrence M. Nelson, captain; David M. Craig, first lieutenant; Robert A. Green, first lieutenant; John R. Haserick, first lieutenant; Charles G. Polan, first lieutenant; Vern C. Strough, first lieutenant, and Rodney F. Sturley, first lieutenant, all of the Medical Corps.

Surgical Service—L. Haynes Fowler, lieutenant colonel; Edward T. Evans, major; Jerome A. Hilger, major; John R. Paine, major; A. G. Plankers, major; Wallace P. Ritchie, major; George S. Bergh, captain; Meyer Z. Goldner, captain; Conrad J. Holmberg, captain; Karl E. Sandt, captain; Leonard Itrud, captain; Lyle French, captain; Lyle Hay, captain; Herman Koschnitzke, first lieutenant; Richard E. Reilley, first lieutenant; Baxter A. Smith, first lieutenant; Vincent Swanson, first lieutenant; Arnold Kremen, first lieutenant; Frederick B. Mears, first lieutenant; Dr. G. Howard Hall, first lieutenant, all of the Medical Corps.

Laboratory Service—Robert Hebbel, major; Evrel Larson, captain, Medical Corps.

Dental Service—Earle W. Nelson, major; Charles Peterka, captain; Harold G. Worman, captain; Lyle A. Brecht, first lieutenant; Virgil R. Ohlen, first lieutenant, and Anthony J. Scholtis, first lieutenant, Dental Corps.

Officers and nurses of the unit were honored at a dinner at the Coffman Memorial Union, February 10. Nearly 1,000 persons attended. Dr. W. A. O'Brien was master of ceremonies.

Dr. H. S. Diehl, dean of medical sciences, spoke on the organization of the unit and the personnel of sixty medical and dental officers and 125 nurses (the latter have the rank of second lieutenant in this war).

Miss Cecelia Hauge, superintendent of nurses at the University Hospitals, who heads the nurses' unit, introduced the hundred or more nurses present who had been recruited from the Red Cross Reserve.

President W. C. Coffey, in his talk, mentioned the loss of faculty members who had entered the service. Dr. E. E. Novak of New Prague represented the Board of Regents.

Major General E. A. Walsh addressed the gathering in the absence of Governor Stassen. He described the hardships which are expected, but pointed out that the satisfaction of service would be worth the hardships. Dr. S. Marx White told of some experiences of the University Base Hospital No. 26 in World War I, and announced the collection of a fund of \$2,100, raised by a special committee which included members of the former Base Hospital No. 26, the sum to be at the disposal of the commanding officer of the hospital unit or unlooked for exigencies.

Mrs. Arthur Law, whose husband commanded the former University Base Hospital No. 26, then presented the new unit with a United States flag, signifying the carrying on of the spirit of the former unit by the new. Lieutenant Colonel L. Haynes Fowler closed the meeting by expressing the unit's determination to carry on.

PROFESSIONAL PROTECTION

A DOCTOR SAYS:

"To my mind, your protection as well as courtesy in times of stress incurred in a malpractice suit is the greatest consolation that any practicing doctor can enjoy. Were it not for you, well I just don't know what would have happened to me."

THE

MEDICAL PROTECTIVE COMPANY

OF

FORT WAYNE, INDIANA

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

DISEASES OF WOMEN. Harry Sturgeon Crossen, M.D., F.A.C.S., and Robert James Crossen, A.B., M.D. 9th ed. 948 pages. Illus. Price, \$12.50. St. Louis: C. V. Mosby Co., 1941.

The ninth edition of this valuable book is a worthy successor to the previous editions. This work has been regarded as an authoritative text on gynecology for over thirty years.

This book is in no sense an operative gynecology and does not purport to be such. Great stress is laid upon the physiologic aspects of the specialty; diagnosis and treatment are particularly well covered.

The latest developments in endocrinology are well discussed. This subject, instead of being delegated to one chapter, is covered in different portions of the work relating to the organ under discussion.

There are many beautiful colored illustrations which are new, as well as a large number of black and white drawings.

The whole subject is well covered and there is a chapter on diseases of the anorectal region as well as one on mediocolegal points.

The book as a whole is very well written and planned. It is easy to read and should be on the "must" list for any gynecologist.

J. R. MANLEY, M.D.

CARDIAC CLINICS. Fredrick A. Willius, B.S., M.D., M.S. (in Med.). 276 pages. Illus. Price, \$4.00. St. Louis: C. V. Mosby Company, 1941.

This interesting and compact 267-page monograph from the Mayo Clinic does indeed make stimulating reading. These informal chats covered in few pages drop plenty of nuggets for those physicians who do general practice and want to intelligently treat their patients afflicted with heart disorders. Internists themselves can learn much from its meaty pages. There are many books written about the heart but this book, it would seem, finds its greatest merit in its practicability.

The book is divided into fourteen chapters. It is well indexed. The first chapter, for instance, is devoted to the "Signs and Symptoms" of heart disorders. Succeeding chapters are devoted to "Diseases of the Pericardium," "Rheumatic Heart Disease," "Bacterial Endocarditis," etc. Phases of disorders of the heart and treatment are briefly but adequately discussed in typical clinic fashion. In the latter chapters, XIII and XIV, entitled "Historic Excerpts" and "Miscellaneous Topics," much of interest is divulged as well as apt treatment given of certain of the homely bits of philosophy in the practice of medicine. This always makes for pleasant reading for the younger doctor.

In a very readable and easy manner, these clinics usually begin with a short history of the case, results of the examination, and later a discussion revealing the instructive elements in each case. Questions and their answers are often included. The style is intimate and clear. The volume is well illustrated with clinical records, electrocardiograms, and pathologists' specimens.

This monograph, as is stated in its foreword, is a compilation of previously published Cardiac Clinics from the "Proceedings of the Staff Meetings of the Mayo Clinic." Many readers of the "Proceedings" will recognize the cases from that source. They are now made available for more ready reference.

SIMON G. SAX, M.D.

MANUAL OF CLINICAL CHEMISTRY. Miriam Reiner, M.Sc., Assistant Chemist to The Mount Sinai Hospital, New York. Introduction by Harry Sobotka, Ph.D., Chemist to The Mount Sinai Hospital, New York. With 18 illustrations. 296 pages. Price, \$3.00. New York: Interscience Publishers, Inc., 1941.

Starting as a mimeographed syllabus of a few directions for interns for emergency procedures this book has more than doubled in bulk within the last ten years. The methods are presented with brevity, conciseness, accuracy, simplicity and in an appealing form. The most recent reference is given for the various procedures, and with The Mount Sinai Hospital modification in some cases. The tables, the standardization of solutions, and the normal values presented are invaluable. It is recommended by the reviewer that so time saving a manual be revised frequently.

DIABETES. Practical Suggestions for Doctor and Patient. Edward L. Bortz, A.B., M.D., F.A.C.P., Associate Professor of Medicine, Graduate School of Medicine, University of Pennsylvania; Chief of Medical Service B, The Lankenau Hospital, Philadelphia; Assistant Editor, The Cyclopedia of Medicine. Second Edition Revised and Enlarged. 296 pages. Price, \$2.50. Illus. Philadelphia: F. A. Davis Co., Publishers, 1940.

Dedication: "In Memory of My Father."

In his Foreword, Dr. George Morris Piersol has aptly written, "His efforts are worthy of success and his text should be welcomed alike by patients, physicians, dietitians, nurses and all who are interested in the farflung problem of diabetes." The reviewer seconds Dr. Piersol's recommendation.

LILLIAN L. NYE, M.D.

ESSENTIALS OF DERMATOLOGY. Norman Tobias, M.D., Senior Instructor in Dermatology, St. Louis University, St. Louis. Pp. 497, with 143 illustrations. Cloth. Price, \$4.75. Philadelphia, Montreal and London: J. B. Lippincott Company, 1941.

Tobias presents a compact book of approximately 500 pages dealing with the essentials of dermatology with special reference "as far as is practical" to the relationship of dermatology and internal medicine. The book opens with a basic survey which includes material pertaining to history taking, etiologic factors, exciting causes, general diagnosis, special diagnostic methods, and a brief discussion of the functions, anatomy and pathology of the skin.

Including the basic survey there are thirty-two chapters, dealing with the erythema group, eczemas, drug eruptions, psoriasis, bullous diseases, pyodermas, paraitic diseases, virus diseases, lichen planus, diseases due to psychic disturbances and physical agents, deep infective dermatoses, tuberculosis, syphilis, tumors, metabolic dermatoses, pigmentations, erythmodermas, diseases of the appendages, scalp and mucosæ. There is one chapter devoted to dermatologic therapeutics.

The accepted modern concepts in dermatology are incorporated and the literary style is good. The 138 half-tone illustrations are excellent. The paper on which the book is printed is good and the type is clear and legible. The book should be of definite value for ready reference for the practitioner and especially the student.

CARL W. LAYMON, M.D.

FIRST AID IN EMERGENCIES. Eldridge L. Eliason, M.D. 260 pages. Illus. Price, \$1.75. Philadelphia: J. B. Lippincott Co., 1941.

This is a very concise and complete little volume which is easy to read; understandable and simple. It is obviously written for the layman but many of the facts ordinarily sufficient for lay purposes are supplemented with further emergency treatments which are to be used only if a physician is not available. (This applies particularly to the reduction of some common dislocations.) This makes it a handy book to keep available in the car or on the person in isolated places.

I believe that the addition of the chapter concerning common contagious diseases together with a discussion of known facts in regard to their transmission and more usual symptoms in this first aid manual, is a very worth-while feature.

S. A. PATTERSON, M.D.

INFANT NUTRITION. A Textbook of Infant Feeding for Students and Practitioners of Medicine. W. M. Marriott, M.D., and P. C. Jeans, M.D. Third Edition, 475 pages. Illus. Price, \$5.50. St. Louis: C. V. Mosby Company, 1941.

This book continues to be a thorough, up-to-date treatise on infant feeding. It is easily understandable, at the same time comprehensive in scope, and may well serve as an excellent reference volume for students, general practitioners, and pediatricians alike. Dr. Jeans, who edits the book for the first time, has succeeded in incorporating his own views into the subject matter without sacrificing any of its outstanding simplicity.

CARL O. KOHLBRY, M.D.

V SYMPHONY HAS GOOD TONES FOR AIR RAID SIREN

The first four notes of Beethoven's Fifth Symphony which signal Morse code "V" for "Victory" could be used as the tone range for air raid sirens.

National Bureau of Standards tests of various siren tones show that a semi-musical note anywhere within the musical scale from A below middle C to C above middle C is best heard against city noises. Physicists will recognize this range as between 200 and 500 cycles.

The first four notes of Beethoven's Fifth are three G's and E flat, well within the recommended range. —*Science News Letter*, February 7, 1942.

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

CHILDREN ADMITTED

28% LESS NICOTINE IN THE SMOKE—BUT NO REDUCTION IN SMOKING PLEASURE

WHEN improving a patient's smoking hygiene, many a physician simplifies his program by advising the regular use of Camel cigarettes—the slower-burning brand. Medical-research authorities* state, and Camel's scientific tests on hundreds of samples** confirm, that a slower-burning cigarette produces less nicotine in the smoke.

Nicotine, as the body of scientific research agrees, is by far the leading component of tobacco smoke having systemic potentials.

Slower-burning Camels not only offer a reduction of nicotine in the smoke but assure your patients of more mildness, coolness, and flavor. Naturally, your recommendation of Camel cigarettes helps to promote patients' cooperation.

● In recent laboratory tests, Camels showed 28% less nicotine in the smoke itself than the average of the 4 other largest-selling brands tested—less than in the smoke of any of them. In the same tests, Camel burned 25% SLOWER than the average of the 4 other largest-selling brands tested—slower than any of them.

1 One of many 3,000-gallon converters in which Dextri-Maltose is processed. Interior being thoroughly cleansed by hand prior to steam sterilization.

2 Steaming under 20 pounds' pressure assures sterility of the huge converters for processing Dextri-Maltose.

3 Sanitary piping — short lengths and readily detachable — is used for conveying Dextri-Maltose. Sections of pipe being cleansed prior to sterilization by live steam pressure.

All DEXTRI-MALTOSE Equipment Is Sterilized by Live Steam Pressure

PHYSICIANS frequently express surprise that the cleansing and steaming of equipment for manufacture of Dextri-Maltose produces sterility comparable to that in hospitals. Huge autoclaves in the Mead Johnson factory steam-sterilize the smaller equipment, and live steam is forced under pressure into storage and processing tanks. This is but one of many precautions taken to make Dextri-Maltose a *carbhydrate safe for infants*. Unremitting care in laboratory and factory has resulted in a product which over a 4-year period has had an average bacterial count well under 100 per gram! Every step in the process of making Dextri-Maltose is under the eyes of competent bacteriologists.

4 Movable equipment used in the manufacture of Dextri-Maltose is sterilized in large hospital-type autoclaves at 20 pounds' steam pressure (259°F. for 20 minutes).

5 Steam at 20 pounds' pressure sterilizes Dextri-Maltose filter presses which remove protein and fat.

These
Prints

No other footprints are exactly the same as those of this newborn infant. And no other oxytocic product duplicates Pitocin,* which helped bring this baby into the world. Pitocin contains the oxytocic principle of the pituitary gland with almost none of its pressor principle. Thus, it effectively stimulates uterine contractions without raising the blood pressure . . . an especially useful factor when labor is complicated by such conditions as nephritis and hypertension.

Pitocin is a familiar product in most delivery rooms. Obstetricians are pleased with its oxytocic reliability, its speedy action, the rarity of systemic reactions following its use. The Parke-Davis label assures accurate standardization.

Chief indications for Pitocin (alpha-hypophamine) are: medical induction of labor; stimulation of the lagging uterus during labor; prevention and minimizing of postpartum or late puerperal hemorrhage; and of blood loss following cesarean section or curettage. Literature on request.

OVER 75 YEARS OF SERVICE TO MEDICINE AND PHARMACY

Highly practical *for* **INFANTS and CHILDREN**

INCORPORATING the daily dose of vitamin D in milk removes some difficulties in administration. The mother merely needs to add the prescribed dose to the daily ration of milk. Moreover, biologic and clinical investigations have shown that when vitamin D is thoroughly diffused in milk smaller doses may suffice for the prevention and cure of rickets.

Drisdol in Propylene Glycol makes it possible to secure the benefits obtainable from combining vitamin D with the daily milk ration. Unlike oily preparations, Drisdol in Propylene Glycol diffuses readily in milk and when well diluted imparts no taste nor odor.

HOW SUPPLIED:

Drisdol in Propylene Glycol—10,000 U.S.P. units per gram—is available in bottles containing 5 cc. and 50 cc. A special dropper delivering 250 U.S.P. vitamin D units per drop is supplied with each bottle.

Q. I've heard that canners just use the surplus crops. Is that true?

A. No. As a matter of fact, many of the varieties used for canning can not be obtained in any other form. Most canners contract for their crops for canning, months in advance. They usually specify the variety of fruit or vegetables wanted. And in many cases this means furnishing seeds or plants especially developed for their purposes. (1)

HAY FEVER

NOW IS THE TIME to defend your patients against hay fever sensitivity. The preseasonal use of Lederle's modern methods of diagnosis, classification and treatment will often make innocuous the guilty air-borne invaders.

The strategy should include the following tactics:

- 1 - determine degree of sensitivity through the single scratch test with the proper Pollen Diagnostics;
- 2 - calculate suitable dosage indicated by the quantitative results of the tests;
- 3 - simplify the testing and treatment by using representative Pollen Diagnostics and Antigens;
- 4 - test for House Dust as a preliminary measure and avoid this complicating factor;
- 5 - finally, remember Lederle's Glycerinated Pollen Antigens offer the important advantages of stability, bacteriostatic properties and minimal reactions.

We will be glad to hold a "council of war" with you on difficult cases. Lederle's experience in the field of allergy spans a period of over a quarter of a century.

FOR SALE BY SURGICAL DEALERS AND DRUGGISTS

THE FRONT LINE IS ON MAIN STREET

All-out efforts for a successful conclusion of hostilities demand the hands, brains and hearts of every American. Maintenance of maximum efficiency requires a healthy, well-nourished body. Our men in the armed forces are assured of nutritionally balanced meals, but, the folks at home also need proper nourishment so that they can do

their jobs . . . so important to the men in the field.

COCOMALT, daily, is an excellent "defense" addition to meals. More and more, physicians are recommending this delicious drink for the entire family. This enriched food drink contains vitamins A, B₁ and D as well as the minerals, calcium, phosphorus and iron.

A New Clinical Study has again shown the value of COCOMALT in therapeutic diets. Have you sent for your copy of "The Use of a Malted Food Preparation as a Dietary Supplement in Pulmonary Tuberculosis"?

MEDICAL CAUSES OF REJECTION IN SELECTIVE SERVICE REGISTRANTS

C. A. McKINLAY, M.D.
Minneapolis, Minnesota

THE nature of physical causes of rejection for military service has important implications not only from the viewpoint of the state of preparedness of the nation but also from that of disease tendencies in relation to the practice of medicine and to preventive medicine. Considerable discussion has taken place with regard to causes of physical disability in registrants, sometimes with emphasis upon supposed inadequacy of medical care.

It is with considerable interest that analysis has been made of the records of registrants examined by the writer as a member of the Medical Advisory Board of Hennepin, Sherburne, Scott, Wright and Carver counties, District I, comprising urban as well as rural communities. This represents only a small sample with limited value compared to total summaries. Of 209 men consecutively examined who were recommended for rejection or placement in limited service classification it is to be noted that the conditions responsible fell within the field of internal medicine and, therefore, that visual, dental, orthopedic defects and hernia which predominate as total causes of rejection are not included herein. Each individual had received his initial examination by a practicing physician who had volunteered to give this service in his office according to the intent of the selective service regulations. Special laboratory examinations including electrocardiograph and determination of the basal metabolic rate and sugar tolerance have been done only when indicated.

It is seen (Table I) that disorders of the cardiovascular system lead as a cause of rejection and, of these, hypertension and neurocircula-

tory asthenia are most common. Sustained elevation of blood pressure of 150 mms. of Hg systolic or 90 diastolic on two or more observations was the criterion. Attempt was made to reduce to a minimum by rest periods the immediate exciting factor of physical examination, an unusual event for a majority of these individuals. No renal or other somatic causes were demonstrated in the hypertensive group. It appears that the present group, compared to those of effort syndrome described by Lewis⁶ in 1920, have a greater tendency to hypertension either with or without tachycardia.

TABLE I

	Number of cases	Per cent of total
Total number rejected.....	209	
Causes of rejection:		
Total cardiovascular	132	63.1
Neurocirculatory asthenia	55	26.3
Hypertension without tachycardia...	32	15.3
Hypertension with tachycardia.....	23	11.0
Organic heart disease.....	22	10.5

Lewis⁶ emphasized poor reaction to exercise with retarded return of pulse rate to normal; also pulse rates at rest often between 80 or 90 were described sometimes with elevation of systolic blood pressure. Cases with vagosympathetic imbalance or neurocirculatory asthenia, when marked in degree, were rejected according to established standards. Persistent sinus tachycardia was one criterion used in this group although in others evidences of vasomotor instability were difficult to evaluate.

In the group reported upon, the response of the heart rate to a given amount of exercise has not provided critical information because no constancy of physical effort or nervous factors

Presented before the Minnesota Society of Internal Medicine, October 25, 1941.
APRIL, 1942

obtain in exercise tests available under the circumstances of these examinations. While such tests may give a rough estimate as to physical fitness, little of value was obtained in regard to cardiac diseases that was not apparent from other sources. As Smith⁸ mentions, the response

TABLE II

	Number of cases	Per cent of total
<i>Organic heart disease</i>	22	10.5
Chronic valvular disease.....	15	7.1
Congenital defects	2

of an individual with chronic valvular heart disease to exercise tolerance tests may be good whereas that of a normal individual who has led a sedentary life is poor. Often the problem has first centered around elimination of the immediate exciting factor of the examination. Individuals with tachycardia, that is, 100 or over, and hypertension have had a period of recumbent rest for twenty to thirty minutes. This represents the standard basal rest period with reduction of nervous and emotional factors. Observations of pulse rate and blood pressure when these were elevated were made frequently on another day. Cases with persistent tachycardia, over 100, under these circumstances of complete rest have added significance and were considered cause for rejection.

Organic heart disease caused 10.5 per cent of rejections with chronic valvular disease its most common manifestation. In certain instances, particularly the arrhythmias, electrocardiographic study was done at the time of the examination or previous records, obtained through the courtesy of the registrants' physicians, were interpreted and established one instance of paroxysmal auricular flutter and another of paroxysmal auricular tachycardia. In others absence of important findings were noted.

The most common somatic disease found with demonstrable lesion was duodenal ulcer occurring in 17.2 per cent (Table II). The diagnosis was established after study by the roentgenologist in thirty-three cases and was suggested by the clinical history in 73 per cent of cases and was

consistent with symptoms in the remainder. The duration of symptoms varied from six months to twelve years. The comparative frequency of duodenal ulcer found is in keeping with the recent experience in the British forces of similar age group reported by Payne and Newman.⁷

Pulmonary tuberculosis	1	

They found that 14 per cent of evacuated cases had peptic ulcer. Of a sample of 287 gastro-intestinal cases 89 per cent had gross disease, almost all ulcers, the majority of which were duodenal. In 92 per cent of the individuals they were present before the war. These observers considered that the most important factor leading to symptoms is in the change from a relatively strict diet to army food. *The Lancet*⁹ stated editorially that from several points of view peptic ulcer was the most important medical problem of the current war.

The diagnosis of hyperthyroidism was made in 7.6 per cent and established by the clinical picture and increased basal metabolic rate. Asthma and hay fever, nephritis and diabetes mellitus were less frequent causes of rejection or of limitation of service (Table III). A report of causes of rejection throughout the state, furnished through the courtesy of Colonel R. B. Hullsiek,⁵ Medical Officer State Selective Service Headquarters, contains total figures only for cardiovascular and gastro-intestinal causes whose ratio was approximately seven to one. This compares with that of three to one herein reported of total number of cardiovascular causes compared to duodenal ulcer. This variation may be explained in part by greater facilities for gastro-intestinal roentgen ray examination available in this district.

The infrequency of infectious diseases including pulmonary tuberculosis raises the question of the adequacy of the means available for case

detection. Undoubtedly the ideal method would include a roentgen film of each registrant as a part of the initial examination as is done in certain areas. In the cases herein reported whenever history or physical signs have suggested possible pulmonary disease a film of the chest has been made (71 cases). In one instance were shadows suggestive of fibroid pulmonary tuberculosis found by the roentgenologist; in another bronchopneumonia was found which cleared within a few weeks. It would appear that the possible chance of oversight of pulmonary tuberculosis in this group has not been great.

It is seen upon analysis that preventable communicable disease was rare in this group. Chronic valvular disease, the chief organic disease found other than duodenal ulcer, is not at this time a preventable disease. The emphasis placed upon nervous and emotional as well as nutritional factors as related to the origin and behavior of duodenal ulcer hardly places it at the door of medical neglect. Hofmeyr⁴ has called attention to the rarity of peptic ulcer in the primitive South African and quotes Eagle and Gilman, who on the basis of combined statistical studies of necropsy material concluded that the average European was seven times more susceptible to peptic ulcer than the Bantu. Poor dietary habits indicative of nutritional deficiency sometimes present before onset of duodenal ulcer likewise have often economic and social rather than medical bearing. Hypertension likewise is relatively uncommon in the Orient according to common reports from physicians who have practiced there. If in addition to hypertension and neurocirculatory asthenia, duodenal ulcer is added to the general category of disease in which nervous and emotional factors are important in pathogenesis or course, it is seen that approximately 70 per cent of all rejections are included therein. It is interesting to note that Paul D. White⁹ discussing the 1938 report of the Surgeon General noted that neurocirculatory asthenia has been taken from the heading of circulatory disease and placed under diseases of the nervous system. Boynton and Diehl¹ in a survey of univer-

sity students subject to registration for the Selective Service noted that the large majority who were given restricted classifications because of physical defects had defects which were not correctible so far as army service was concerned.

Cannon² has emphasized the effects of the emotions on bodily functions and believes that the medical profession has not appreciated the influence of the nervous and emotional strain as a cause of disease and has not realized in a practical way the recent shift from the infections in the etiology of disease.

While realizing that any generalization with regard to diseases of unknown origin such as non-renal hypertension, neurocirculatory asthenia and duodenal ulcer is valueless, it is of interest that as leading causes of rejection they are characteristic of American and European civilization rather than that of peoples of more primitive living habits. The causes of rejection herein reported in no sense represent failure of the practice of medicine or of preventive medicine.

Summary

1. Essential hypertension (26.3 per cent) and neurocirculatory asthenia (26.3 per cent) were the chief causes of recommendation for rejection among 209 registrants disqualified or qualified for limited military service only. Preventable infectious diseases were rarely found.

2. The chief somatic disease found with demonstrable lesion was duodenal ulcer (17.2 per cent) followed in frequency by organic heart disease (10.5 per cent) and hyperthyroidism (7.6 per cent).

INJURIES OF THE NOSE

CARL W. WALDRON, M.D., D.D.S.

Minneapolis, Minnesota

WOUNDS of the nose result from a great many forms of trauma and may present variations in the types of injury or loss of the skin and supporting bony and cartilagenous structures. Contusion and laceration may be very marked or slight, and the wound may be at right angles to the skin or oblique and undermined, exposing an extensive portion of the underlying tissues. Nasal injuries are frequently associated with fractures of the upper jaw, the malar bone, head injuries, or with other serious injuries that may receive active treatment before the wounds of the nose may be taken care of in a thoroughly efficient manner.

The immediate treatment should be directed towards the prevention and control of shock and hemorrhage if present. Bleeding into the throat with consequent respiratory obstruction in a severely depressed or partially conscious patient may be very serious and later pulmonary complications may ensue from the inspiration of blood, mucus, or foreign bodies into the lungs. Partially separated flap-like portions of the nose should be replaced and gently supported by gauze dressings to avoid undue pressure and possible interference with the blood supply of a nearly detached portion of the ala or tip of the nose.

The wounds should be cleansed of blood clots and debris, or any foreign bodies that may be present. For this purpose, soap and water and hydrogen peroxide have been found most useful. The wound margins should be retracted with fine skin hooks and all foreign bodies should be carefully removed in order to promote healing. Lacerated and contused skin margins may require conservative débridement, and the sharp excision of ragged edges will facilitate suturing and diminish the amount of scarring of the skin that will subsequently occur. Portions of contused skin may be found almost completely detached, necessitating excision to prevent loss of the affected skin from sloughing. Lacerated wounds of the nose, if extensive, may permit adequate inspection of the fractures of the underlying bony structures. The parts may then be reduced under visual control. One must resist

the temptation to remove partially separated fragments of bone and cartilage, for in practically every case they may be retained to aid in the healing and stabilization of the supporting structures. Those small pieces of bone sequestrate so rarely that their retention should be the rule.

The suturing of wounds of the nose should be undertaken with a due sense of responsibility regarding the ultimate scar and the contour of the external nose. Far too frequently, one sees such wounds closed with interrupted sutures of stiff dermal or even silk worm gut, using needles many times too large. If a surgeon finds it inconvenient to use the finest of suture material, such as Deknatel A threaded on arterial needles, he should keep on hand tubes of plastic sutures threaded on fine eyeless needles, or refer the patient to a surgeon who will close the lacerations in a proper manner. Careful subcuticular suturing is being used more and more by plastic surgeons because the sutures may be left in for ten days to two weeks in order to maintain the close approximation of the skin margins. Interrupted sutures of Deknatel A may then be used sparingly where needed for fine approximation, and removed in two or three days without producing stitch marks. A slightly heavier suture, Deknatel B, or fine horse hair suture is excellent for the subcuticular suturing. When the wound is of any considerable length, it is best to bring the suture out through the skin at intervals of three-fourths of an inch, and then reinsert the needle to continue the subcuticular closure. This facilitates the removal of the suture because it may be divided where it is exposed through the skin, and removed in short lengths. Care should be taken to secure all bleeding points that continue to ooze after clamping, by ligation with very fine catgut or silk, because a hematoma may seriously interfere with the healing of the parts. In undermined wounds with a number of fine bleeding points, ample drainage is essential. This may be secured by using a small strip cut from a Penrose drain or a strip of cellophane, to be removed in one or two days. A small vaseline strip of fine mesh gauze is then placed over the

wound, over which a pressure dressing is applied. Badly contaminated wounds should be insufflated with powdered sulfanilamide before suturing.

Actual loss of nasal skin should be restored by immediate skin grafting unless the wound is so obviously contaminated that efficient cleansing is unlikely to be successful, or where a surface of bone is exposed that cannot be covered by suturing the subcutaneous tissues. Full thickness grafts from the postauricular region are the most satisfactory from the standpoint of color and texture. They should be sutured in position under slight tension and maintained under moderate pressure by means of a dental wax or compound splint or a metal splint. When the graft is situated laterally at the base of the nasal bridge, efficient stabilization and pressure may be secured by leaving the marginal fixation sutures long and tying them over wax or a dental cotton roll. The dressings should be left undisturbed for a week or ten days unless the need for more efficient stabilization or pressure seems indicated. There can be no doubt that cosmetic results would be better if immediate skin grafts were employed more frequently in cases of traumatic loss of the nasal skin.

Fractures of the Nasal Bones

These fractures are probably the most commonly seen in practice, and it is to be regretted that all too frequently they do not receive the attention they deserve. This is due to a rather general disposition to consider nasal fractures and resultant cosmetic deformities as matters of minor importance together with the fact that the initial swelling of the adjacent soft tissues may disguise the presence of underlying fractures with displacement. The great advances in rhinoplastic surgery of the past decade have given surgeons a better understanding of underlying displacements and reasons for the deformities of the nose that result from the various types of nasal injuries. Consequently, many of the disfigurements that heretofore have been considered unavoidable are now known to be definitely amenable to treatment. One must guard against the temptation to neglect the fractured nose in children. Swelling, tenderness and the usual difficulties encountered in examining and treating children may make the diagnosis of fractures and displacements of the nasal bones and cartilaginous septum a matter of considerable difficulty. It is

a fact that both children and adults are much more appearance-conscious than formerly was the case and that noticeable nasal deformities assume considerable psychologic and economic importance in this competitive age.

Classification of Fractures of the Nose

(Modified from Safian and Tamerin)

I. Simple Fractures

- A. Fractures of the nasal bones and frontal processes of the maxillae.
 1. Linear fractures without displacement.
 2. Fractures with displacement and deformity.
 - a. Medial depression of one nasal bone and frontal process.
 - b. Lateral deviation, due to medial depression of one nasal bone and frontal process with lateral displacements of the bridge and the opposite nasal bone and process; also displacement of the nasal septum.
 - c. Depression of the bony bridge.
 - d. Widening of the bony bridge and bases of the nasal bones and frontal processes of the maxillae.
- B. Fractures of the nasal septum.
 1. Without deformity.
 2. With displacement and deformity.
 - a. Depression of the septum.
 - (1) Saddle nose.
 - (2) Dropped tip.
 - (3) Obstruction of respiration.
 - b. Deviation of the septum.
 - (1) Without external deformity.
 - (2) With external deformity.
 - (a) Protruding septum.
 - (b) Deviation of alar cartilages.
 - C. Combined fractures of the nasal bones and the septum.

II. Compound Fractures—including Complicated Fractures.

Signs and Symptoms

Hemorrhage from the nasal cavities is present in most fractures of the nose. It may be slight in amount and cease spontaneously or may be profuse and continue to exsanguinate the patient unless promptly controlled and arrested. Bleeding may be from one side only if but one nasal bone is fractured and depressed. The bleeding is due to the rupture of the nasal mucous membranes by the bony fragments.

Ecchymosis and swelling result from the extravasation of blood into the subcutaneous tissues. This may be unilateral or bilateral and varies considerably in amount and position. The eyelids may be involved to a marked degree, and the extravasation may extend to the cheeks or

Fig. 1. Roentgenograms showing fractures of the nasal bones.

Deformity may not be noticeable unless the nasal bridge has been displaced from its midline position or has been depressed. One may readily overlook lesser deformities because they are frequently masked by swelling of the soft tissues.

Diagnosis of Fracture of the Nose

One must suspect fractures with minor displacements in all cases of injury to the nose until swelling, discoloration, and tenderness of the overlying soft parts and of the eyelids have been proved to be due only to contusion and not to an associated bony injury. Impaired nasal breathing space and bleeding from the nose usually indicate fractures and careful intranasal examination should be made in every case. This often gives one valuable information regarding fracture displacements of the bony and cartilagenous septum as well as displacements of the nasal bones. X-ray examination (Fig. 1) is usually more a matter of confirmation of the clinical diagnosis than a necessity in the handling of these cases. A carefully exposed lateral X-ray film may, however, be of decided value in the diagnosing of a depressed fracture of the lower portion of the bony bridge which might otherwise be completely masked by swelling (Fig. 1A).

Anatomic Pathologic Considerations

even to the neck. Ecchymosis and swelling usually appear soon after the injury, but it may be almost twenty-four hours before these symptoms become manifest. They may increase for another day or two and then subside to disappear in about ten days' time.

Nasal obstruction is a frequent symptom and may be due to a combination of blood accumulation, swelling of the nasal mucosa and a fracture displacement of the nasal septum. Subperichondreal elevation of the septal lining mucosa from the cartilage by hemorrhage may produce an obstructive hematoma. This should be looked for to permit surgical evacuation of the blood in order to avoid subsequent infection and abscess formation which, in turn, might be followed by destruction of the septal cartilage with the dropping of the cartilagenous bridge to produce a saddle nose.

Pain is rarely severe, and manipulation of the nose may elicit but moderate tenderness. Bony crepitus is usually felt when the fractured parts are manipulated or repositioned by the fingers.

The arch of the bony bridge is composed of the two (paired) nasal bones and the frontal processes of the superior maxillae supported in part by the bony and cartilagenous septum (Fig. 2). Below the nasal bones, the bridge is composed of the anterior margins of the two lateral or triangular cartilages supported by the septal cartilage which projects between them to a variable degree. The lower portion of the nasal bridge is composed of the upper margin of the septal cartilage alongside of which approximate the upper inner borders of the alar cartilages. In combined fractures the component parts of the nasal septum, the vomer, quadrilateral cartilage and the perpendicular plate of the ethmoid are involved and displaced by fracturing or by fracture dislocations. Any of the component bony and cartilagenous parts of the nose may be involved in fractures with resulting displacements, hemorrhage and swelling.

Fig. 4. Methods used to hold the nasal bones in position. A. Cotton rolls. B. Bandage rolls. C. Dental compound splint. D. Metal splint (brass or aluminum).

Treatment of Fractures of the Nose

Hemorrhage must be controlled by local means, such as intranasal tampons or packing applied for a few minutes or left in position for twenty-four hours if necessary. External pressure by a molded splint may be of service in the control of bleeding and the prevention of a hematoma. In most cases, however, bleeding either stops spontaneously in a few minutes or after nasal packing which may be removed in a short time. One must watch for the presence of a hematoma of the external tissues or of the septum in order to evacuate the blood surgically by external or intranasal incisions.

Swelling and ecchymosis cannot be effectively controlled and usually runs its course. Cold compresses may reduce the swelling to some degree.

Pain may be absent, and if of any consequence, may be controlled by aspirin, codeine, and other sedatives. Blood clots may be removed from the

nasal cavity by the usual methods. The patient should not blow his nose as air might be blown through lacerations to produce an emphysema of the nose or cheek. This might become infected and at best might persist for several weeks.

Primary treatment of fractures of the nose may be undertaken within the first two or three weeks after the injury, i.e., before more or less complete fibrous immobilization of the fragments has taken place. If this period has elapsed, it is well to postpone rhinoplastic procedures for the correction of deformities for several months. By this time, complete healing and circulatory adjustments of the parts will have taken place, and the tissues will react more kindly to the rather severe surgical procedures made necessary for the correction of the displacements and deformity.

Simple linear fractures without deformity usually do not require any active treatment unless a hematoma is present. One must differentiate between an extensive swelling, which may be reduced by gradually applied pressure, and a hematoma, which produces a moderately firm enlargement that cannot be reduced to any extent by externally applied pressure. Such collections of blood and blood clot should be evacuated and pressure applied in order to prevent possible organization of the clot and permanent enlargement of the area.

Unilateral medial depression (Fig. 3) of the nasal bridge is usually due to an impact with a small object. The lines of fracture tend to be multiple and involve both the frontal process of the maxilla and the nasal bone proper. Initial swelling may completely mask this type of fracture though unilateral nasal obstruction and a sense of pressure in the upper portion of the nose on the affected side will usually bring the patient to the physician for treatment. Palpation and manipulation will determine the position of the depressed fragment and whether there also is a slight lowering of the dorsum of the bridge. A small dental x-ray film placed against the side of the nose with minimal exposure often gives valuable information regarding fractures of the lower end of the dorsum of the nasal bones with slight depression. In the event that this type of nasal fracture is not diagnosed during the period of swelling, the driven-in appearance becomes apparent when the swelling subsides after a few days, and there is still ample time for successful

elevation of the depressed fragments. Treatment is relatively simple. The nasal mucosa adjacent to the depressed fragments may be anesthetized by the application of 10 or 20 per cent cocaine

is fractured and carried laterally with the movement of the bony bridge. The resulting deformity is a flattening and depression on the side receiving the blow, with displacement of the dor-

Fig. 5. A. Adjustable Joseph splint used to maintain the medial position of the nasal bones. B. Frontal appliance used to maintain the medial position of the right nasal bone.

solution, using cotton on fine metal applicators. A slightly curved blunt elevator is then inserted high up in the nose between the septum and the depressed fragments. These are elevated and repositioned, aided by manipulation with the fingers on the external surface of the bridge. Slight over-correction of the deformity is indicated. The fragments may be held in position by the insertion of a small high pack of one-half inch iodoform gauze well lubricated with an anesthetic antiseptic ointment. This should be changed every day until the fragments become sufficiently stabilized to maintain their proper position without danger of recurrence of the deformity. An external splint made of brass or aluminum lined with outing flannel or moleskin adhesive (Fig. 4) may be useful in maintaining the alignment of the nose and protecting it from minor pressures or traumatism.

Lateral deviations of the bridge (Fig. 5) are the result of severe blows on the side of the nose which produce fractures of the frontal processes of both sides of the maxilla with transverse fractures of the upper portion of the bridge. The underlying bony and cartilagenous septal support

sum of the bridge to the opposite side. The diagnosis of this type of fracture is usually made without difficulty for the lateral deviation is quite noticeable although extreme swelling may occasionally disguise the fact that the nasal bones are displaced considerably from the median plane.

Repositioning of the displaced fragments may be secured by pressure of the thumb on the convex side. This may be supplemented by the elevation of the depressed side by using a blunt elevator within the nasal cavity. Though one may secure reduction of the displacement at times without anesthesia, it is better to inject novocaine along the lateral borders of the nose and apply cocaine and adrenalin to the nasal septum and the external nasal walls adjacent to the frontal processes of the maxilla. This facilitates more accurate replacement of the fragments and permits careful and firm manipulation unhampered by tenderness of the injured parts. The associated fracturing or buckling of the nasal septum may at times interfere with the repositioning of the nasal bones. In such cases, realignment of the nasal septum may be accomplished by means of a duckbilled Asch forceps (Fig. 6). There may be a tendency for the septum to spring back to-

wards its former displaced position. If so, intra-nasal splinting or packing should be maintained on this one side (and changed daily) until the septum will remain in the median position. Slight

repositioned nose. This compound hardens quickly and may be trimmed and reapplied with adhesive tape. Splints may be made of soft metals such as tin, copper, or alloys or of stiffer metals

Fig. 6. Reconstructed models of depressed fractures of the nasal bones: *A*. Depressed tip. Insets—roentgenograms using dental films. *B*. Depressed fracture of the entire nasal bone.

Fig. 7. Markedly depressed fractures of the bridge of the nose. *A*. Fracture of the nasal bones, frontal processes of the superior maxilla with lateral displacements to override the internal margins of the orbit. *B*. Depressed fracture involving the frontal process of the maxilla, the ethmoidal, lacrymal, and nasal bones.

over-correction of both the septal displacement and the external deformity is indicated in these cases of fracture deviations of the bridge, and the corrected position should be maintained by the use of some form of external support. Dental cotton rolls or bandage rolls, held against the side of the nose by adhesive tape (Fig. 7), may be used. It is difficult, however, to hold these rolls in position and maintain uniform support without undue pressure. Therefore, in most cases, some form of rigid splint should be employed. Dental impression compound may be slightly softened in hot water and moulded over the

such as aluminum or brass. All of these splints should be lined with outing flannel held by mastisol or by moleskin adhesive. If greater lateral compression is needed, one may apply the Joseph or Safian nasal brace (Fig. 8). If there is need for extra pressure on but one side, this may be secured by various types of head bands with adjustable extension arms from frontal plates (Fig. 9). The pressure may be applied by spring action or by the use of rubber bands as described by Kazanjian. Risdon has designed a similar pressure appliance to be attached to a dental splint cemented to the upper teeth. In cases where con-

siderable difficulty is encountered in maintaining the proper position of the septum and tip of the nose and the upper bridge by the methods outlined, the patient should be advised that a per-

cate the treatment and the ultimate result may leave much to be desired.

Very severe traumatism may produce marked comminution of the nasal bones and upper por-

Fig. 8. *A.* Elevation of comminuted fractures of the nose by means of metal plates and through and through silver wires (J. B. Brown). *B.* Straith appliance for the elevation and support of markedly comminuted fractures of the nasal, lacrimal, ethmoidal bones, and the frontal process of the superior maxilla.

fect result is not always possible. Septal surgery and rhinoplastic procedures may be necessary at a later date to improve the breathing space and to restore the nose to the desired shape and mid-line position. This should be postponed for six months or more.

Depressed Fractures of the Nasal Bridge

Blows on the lower third of the bony bridge frequently result in multiple fractures with slight depressions. Swelling may completely mask the presence of the depression and direct lateral x-rays should be taken using a dental film. If depression is present, the parts should be elevated with a thin blunt elevator and a small amount of lubricated antiseptic packing inserted high up to support the bones. The packing should be changed at least every other day.

Greater traumatism may fracture the nose through the frontal processes of the maxilla lateral to the nasal bones, and the fractured edges may spread laterally to override the basilar portions of the frontal processes. The nasal half of the bony bridge becomes markedly flattened and widened. Intranasal elevation of the parts followed by packing and external manipulation followed by the application of Safian or Joseph external splints will usually correct the deformity. Septal fracturing and overriding often compli-

Fig. 9. Asch septum straightening forcep used to reposition the nasal septum in the mid-line where it is maintained by intranasal splints and packing.

tions of the nasal processes of the maxilla with extreme depression of the fractured parts. The nasal bridge is driven backwards into the ethmoidal region to fracture the ethmoidal bones on both sides, and the inner margins of the orbital rims are displaced externally. The inner canthi are consequently displaced externally and frequently downward to a considerable extent to produce a very distressing deformity. In cases of this type, attempts to reposition the nasal bridge should be postponed for at least ten days in order to prevent if possible the development of meningitis. Treatment of these severe injuries is naturally complicated and painstaking. The Straith appliance is excellent for the elevation and support of the nasal bone:

"Two rubber covered wire splints are inserted into the nostrils. By a simple mechanical device, these splints may be elevated, tilted to various angles, or shifted laterally, as the situation may require. The bridge may thus be maintained in proper position for several weeks. Two lateral pressure pads may be applied and adjusted separately to prevent spreading of the nasal fragments."

We have added an upper jaw dental splint to the Straith appliance to give additional support and fixation of the lower end of the vertical bar carrying the intranasal wire splints and lateral pressure pads. The greatest difficulty encountered in the treatment of these fractures is the correction of the external displacement of the orbital rim, and the subsequent maintenance of the fractured parts in their correct position.

Occasionally, a severe blow may completely separate the nasal bones from the glabella at the suture line, and the entire nose may drop a quarter of an inch or more. Usually, this type of fracture will be associated with a high horizontal complete fracture of the maxilla. The management of these combined fractures is that of the treatment of fractures of the maxilla in that the measures employed to raise and support the maxilla will usually elevate the nasal bones to their proper position in contact with the glabella. Should the maxilla not be fractured or reduction not complete, the nose may be brought up and its position maintained by drilling small holes through the nasal process of the frontal bones and through the upper end of the nasal bones—a 24 or 26 gauge silver wire passed through the holes and twisted will secure the bones in correct position.

Fractures of the Nasal Septum

Fractures of the nasal septum may result from a blow on the lower half of the nose, and may occur without appreciable external deformity at the time of the injury. Cartilage unites by fibrous union, which may not adequately support the overlying cartilages and skin, and in course of time contraction of the scar plus minor traumas may produce deformity of the lower half of the nose. The treatment indicated is the routine control of nasal hemorrhage, the evacuation of a hematoma if present, followed by packing to prevent its recurrence. Every effort should be made to prevent the formation of a septal abscess.

Fractures of the septum with deformity are of several types.

1. A saddle nose with but a slight depression, or to the extent that a deep hollow is produced when the septal cartilage is fractured near its junction with the tips of the nasal bones.

2. Fractures at a lower level may be accompanied by a dropping of the tip cartilages.

3. Overriding of fractured portions of the septal cartilage may occur without deviation, and there will be varying degrees of nasal obstruction. The immediate treatment of these conditions is not very satisfactory, and it usually becomes necessary to resort to rhinoplastic surgery to restore the contour of the bridge or raise the tip after several months have elapsed. Submucous resection of the nasal septum is frequently indicated.

Fracture deviations of the nasal septum may occur with internal deformity, with external deformity, or with both conditions present.

The septal cartilage may be fractured and considerably bent to produce obstruction to breathing without any external evidence of the injury. The treatment consists of replacement of the deviated portion under local anesthesia followed by intranasal splinting or packing to maintain the septum in the midline position.

In some cases, the entire septum is dislodged from its lower attachments and displaced laterally. If the septal cartilage is fractured at the same time and bent or displaced from its attachment to the perpendicular plate, the replacement of the entire septum is usually satisfactory for a time but the cartilage deviation tends to recur, necessitating a submucous resection.

Fracture deviations of the lower portion of the septal cartilage may occur without an accompanying fracture displacement of the bony ridge. The treatment is manipulation of the displaced septum to a slightly over-corrected position to be maintained by intranasal packing reinforced by external splinting or adhesive tape.

The anterior edge of the nasal septum may be dislocated from its attachment to the vomer and may project at the nares with an accompanying deviation of the tip. This should be replaced and held by packing. If recurrence of the dislocation takes place, plastic correction is indicated to improve the breathing space and the appearance. If the nose is too long, it may be shortened at the same time.

Summary

Lacerated wounds of the nose should be treated and sutured with great care in order to restore proper normal contour and alignment and prevent undue scarring.

Injuries of the nose accompanied by swelling or nasal obstruction should be investigated to de-

termine the extent of bone and cartilage injury and displacement to make possible adequate treatment to prevent subsequent deformity.

Fracture dislocations of the nasal septum may frequently be mobilized and manipulated to a reasonably satisfactory midline position. Submucous resection of the nasal septum may, however, be necessary at a later date to relieve nasal obstruction.

TRANSFUSION REACTIONS AND ERYTHROBLASTOSIS FOETALIS CAUSED BY THE RH FACTOR

GEORGE N. AAGAARD, M.D.
Minneapolis, Minnesota

IN 1940, Landsteiner and Wiener⁴ first showed that 85 per cent of humans had in their red blood cells an agglutinin which could be demonstrated if human red cells were tested with serum from rabbits which had previously been immunized by injections of blood from Rhesus monkeys. Humans possessing this agglutinin they designated Rh positive. Approximately 15 per cent of humans lacked this property in their red cells. They were called Rh negative. Reports which have appeared recently indicate that the Rh factor may be the cause of a large number of hemolytic transfusion reactions. A causative relationship to erythroblastosis foetalis now seems likely. In addition there is evidence which suggests that the Rh factor may be of some importance in the production of toxemia of pregnancy.

Transfusion reactions caused by the Rh agglutinogens and agglutinins were first described by Wiener and Peters in 1940.¹³ In their cases the production of the Rh agglutinins in Rh negative patients was stimulated by a first transfusion of Rh positive blood; and a reaction occurred when a second transfusion of Rh positive blood was given later. It is not entirely clear why transfusion reactions on this basis do not occur more often, if the above percentage of Rh positive and Rh negative individuals is correct. Wiener and Peters offer two possible explanations:

(1) that not all Rh negative persons are able to produce Rh agglutinins; (2) that subsequent transfusions of Rh positive blood are either not given or are not given at a time when a high titre of Rh agglutinins is present in the recipient's serum.

Erythroblastosis foetalis, which includes fetal hydrops, icterus gravis, and congenital anemia, has long been an etiological puzzle. In 1938, Darrow² suggested that it might be due to an antigen-antibody reaction between the infant's and mother's blood. In 1939, Levine and Stetson⁵ described a case of transfusion reaction in a woman never previously transfused but who had just delivered a macerated fetus. They suggested that a dominant "immunizing property in blood and/or tissues of the fetus must have been inherited from the father." The mother, lacking this property, was immunized against it by the fetus in utero. In 1941, Levine, Burnham and others published papers,^{1,7} which showed that the Rh agglutinin was the "immunizing property" in a majority of the cases of erythroblastosis foetalis. It was shown⁸ that 91 per cent of the mothers of infants affected with erythroblastosis foetalis were Rh negative, in contrast to the 15 per cent to be expected from the general population. In addition it was shown that 100 per cent of the affected infants and their fathers were Rh positive. It is likely, therefore, that the Rh positive fetus stimulates the production of Rh agglutinins in the mother's blood. The agglutinins formed in the mother gain access

to the fetus, cause lysis of the fetal red cells and produce erythroblastosis foetalis.

In 1905 Dienst³ suggested that toxemia of pregnancy might be due to incompatibility between maternal and fetal blood. McQuarrie⁹ and Ottenberg¹¹ published papers in 1923 supporting this hypothesis. That incompatibility of fetal and maternal blood due to the Rh factors might play a rôle is suggested by the high incidence of symptoms and signs of toxemia of pregnancy which is found amongst mothers while carrying infants affected with erythroblastosis foetalis. This possible relationship certainly merits further study.

Tests for Rh Agglutination

Ordinary agglutination technique will only rarely demonstrate the presence of Rh agglutination. The reaction is most pronounced at refrigerator temperatures. Wiener and Peters¹³ described a sensitive technique which is as follows: One drop of a 2 per cent saline suspension of the donor's cells is mixed with two drops of the patient's serum, the mixture is chilled in ice water and centrifuged five minutes. The tube is gently shaken to resuspend the cells and agglutination is read macroscopically and microscopically. A control with patient's cells and serum is run to rule out agglutination due to an increased titre of "cold" agglutinins.

Recently Levine and co-workers⁶ have described a different technique in which the mixture of donor's cells and patient's serum are incubated first for one hour at 37° C., then centrifuged at low speed for one minute, resuspended by gentle shaking and examined for agglutination as above. It would seem wise to carry out the procedure at refrigerator, room and body temperature if atypical agglutination is likely to be present, since the agglutinins are variable in the temperatures at which they act in vitro.

A further precautionary measure which may be employed is the biological test: the first 50 to 100 c.c. of blood is administered to the patient in not less than one hour. If no reaction occurs the remainder of the blood may be administered at a more rapid rate. That this measure is not completely reliable is borne out by several case reports^{10,12} in the literature in which serious late reactions (oliguria, uremia, etc.) were noted without any immediate untoward symptoms (chills, fever, pain, etc.).

Indications for special studies to prevent reaction caused by the Rh factors are as follows: (1) If repeated transfusions are required for the supportive care of any medical or surgical patient (i.e., blood dyscrasias, chronic blood loss, pre- and postoperative care); (2) Any transfusion during pregnancy or the puerperium particularly if a history of obstetrical complications exists. A list of Rh negative donors should be available on every obstetrical service.

Case Reports

M. H., a twenty-six-year-old white woman, was admitted to the University Hospitals on July 19, 1941. She stated that she had been delivered of a macerated fetus, born at full term on July 6, 1941. A midwife had attended her in the home. Edema of the lower extremities had been present for the last month and a half of the pregnancy, and no fetal movement had been noted for the last month. About ten days' postpartum abnormal bleeding occurred with the passage of large clots. At this time she also noted chilly sensations followed by a sense of warmth. She was admitted to the University Hospitals on July 19 because of these symptoms.

Inquiry into her past health revealed that she had had three pregnancies including her present illness. The first pregnancy was in 1938 and resulted in the birth of a normal male infant. No complications occurred. Her second pregnancy was in 1940, the infant lived only a few minutes and an autopsy revealed erythroblastosis foetalis. This was a full term pregnancy and no maternal complications occurred. The third pregnancy in July, 1941, resulted in a macerated fetus at full term, and the autopsy again revealed erythroblastosis foetalis.

Physical examination at the time of entry to the hospital revealed the following pertinent findings: temperature, 103°; pulse, 110; blood pressure, 125/85. Patient was pale. Abdomen revealed slight distention. The uterine fundus was palpable and tender 15 cm. above the symphysis pubis. There was also slight generalized abdominal tenderness and rebound tenderness. Large blood clots were present in the vagina. No placental tissue could be seen in the cervix.

Laboratory studies revealed the following: Blood group O (Landsteiner), (Group 4 Moss); Hgb. 4.9 Gms.; R.B.C. 2,310,000; W.B.C. 17,700; 86 per cent neutrophils. Urine: Albumin 1+, microscopic negative. Because of the anemia, five transfusions of citrated blood were given. In each case the donor was group O (Moss group 4), and in each case the blood was cross matched before administration and found compatible. Different donors were used for each transfusion. The first transfusion of 500 c.c. was given on July 19 without reaction. The second transfusion, given on July 21, was stopped after 200 c.c. had been given because of a severe chill, following which the temperature rose to 104.2° F. The third and fourth transfusions were given on July 23 and 24 respectively, 500 c.c. each and without reaction. On July 25, 500 c.c. of blood was given with-

but any immediate reaction but a few hours later it was noted that the patient passed grossly "bloody" urine. On July 26, the next day, the urine appeared grossly bloody but no red cells could be found on microscopic examination. On July 29 the blood pressure was 150/90 mm. Hg. Subsequent readings varied widely from 130/90 to 90/90. The blood pressure returned to normal on August 15. The urine showed 1 to 3 plus albumin and varying numbers of red cells, and returned to normal on August 20. The late appearance of erythrocytes in the urine, after the transfusion reaction, was not readily explained. The possibility of glomerular damage or of an actual glomerulitis was considered.

Unfortunately we were unable to obtain blood from the donors used in this case, since they lived at some distance from Minneapolis. However, the patient's serum when tested with the cells of 35 group O donors from our blood bank by means of the cold technique described above, showed agglutination with 77 per cent. With but two of these was agglutination observed when tested by the ordinary cross-matching technique. Red cells from the patient's husband, also Group O, were agglutinated by the patient's serum in dilutions up to 1 to 10. The control with the patient's own cells and serum was negative.

Since, in all the cases tested, the donor's cells did not contain ordinary A or B agglutinogens, it may be concluded that some other agglutinin was present which caused the agglutination observed with the Wiener technique. This fact, together with the history of delivery of two infants with erythroblastosis foetalis, suggests that the Rh factors were the cause.

The second case is reported through the kindness of pathologist, Dr. Frank C. Andrus, and the staff of the department of Obstetrics and Gynecology of the Minneapolis General Hospital.

The patient, a woman aged twenty-nine years, was admitted to the Minneapolis General Hospital on June 5, 1941. She stated that one week previously she had attempted mechanical self-induction of abortion. She was approximately four months pregnant at that time.

Inquiry into her past health revealed that she had had four previous pregnancies. The first resulted in a full term delivery of a normal infant. The next three pregnancies ended in abortion although the stage of pregnancy and nature of the abortions are not known.

The patient was afebrile when admitted to the hospital. She was not bleeding. Attempts at medical in-

duction of labor failed. Mechanical means were tried later. On June 21, 1941, she experienced a sudden hemorrhage. The next day a transfusion of 500 c.c. of homologous Group A blood was administered. A severe reaction began just as the transfusion was completed. The patient suffered a severe chill, the temperature rose to 103.6° F. and hemoglobinuria was noted within a few hours. Oliguria (a 24-hour output as low as 70 c.c. of urine) followed. A mild degree of nitrogen retention was noted. The patient gradually recovered.

Samples of the patient's and donor's blood were sent to Dr. Alexander Wiener. He reported that the patient was Rh negative and the donor Rh positive. Dr. Wiener believed it likely that Rh agglutinins in the patient were responsible for the transfusion reaction.

Summary

1. The role of the Rh factor in the production of transfusion reactions and in the pathogenesis of erythroblastosis foetalis is reviewed.
2. Tests for Rh agglutinins are discussed and indications for their use are stated.
3. Two cases of transfusion reactions probably due to Rh factors are described.

A SIMPLE METHOD FOR THE REMOVAL OF IODIZED OIL FROM THE SPINAL SUBARACHNOID SPACE

EDWARD H. JUERS, M.D. and HAROLD O. PETERSON, M.D.
Red Wing, Minnesota Saint Paul, Minnesota

IN 1919 Dandy introduced air myelography. In 1922 Sicard and Forestier first used Lipiodol in the subarachnoid space as an adjunct in the diagnosis of spinal cord lesions. It has since developed that iodized oil myelography is the most accurate roentgenologic method of determining the presence of a lesion within or encroaching upon the spinal subarachnoid space. Not only can most of the lesions be localized by this method but often it is possible to differentiate between the various types of abnormalities present. However, since these iodized oils are not absorbed from the subarachnoid space and since their continued presence may be harmful in some instances, there has been an urgent need of finding another contrast medium which is absorbable and non-toxic.

The only substances which have met these requirements are the gases such as air, oxygen, ethylene, etc. In recent years gas myelography has become very popular, especially for the diagnosis and localization of posterior herniations of the intervertebral disc. Most observers agree, however, that examinations using gas are less accurate than those using iodized oil and that the interpretation of the gas films is far more difficult. If it were possible to remove the iodized oils all the objections to their use could be dismissed.

When a laminectomy is done following an iodized oil examination it is possible to open the dura and remove some of the oil. However, it is usually not possible to obtain all of the oil.

In 1936 Lucherini described a method for the removal of Lipiodol from the spinal sac, in those cases where laminectomy was not done. He introduced a trocar into the most dependent part of the dural sac and, with the patient sitting up, the oil drained out. He did not obtain complete removal, however. In 1939 Briesen reported one case in which he bored a hole one-eighth of an inch in diameter in the sacrum through which he also introduced a trocar into the dependent dural sac. A long time was required for the oil to run

out and again a complete removal was not obtained. Adson carried out a similar procedure about the same time in which he exposed the caudal sac over an area of seven to ten millimeters by removing a small part of the sacral lamina. He incised the dura and drained the oil off with the patient upright. Adson advocated that this procedure be used only in some of the cases which did not have a laminectomy following the oil examination. All these procedures are not simple, however, and not suitable for routine use.

In March, 1941, Kubik and Hampton reported a procedure in which the oil was successfully removed by simply aspirating it through a spinal puncture needle immediately on completion of the roentgenologic examination. At that time thirty cases were reported and many more have been added since. This effectual method of removal has eliminated all the objections to the use of iodized oils. Since there are so many cases suspected clinically of having a posterior herniation of the intervertebral disc, it is very gratifying to be able to verify this diagnosis roentgenologically using iodized oil knowing that the oil can be removed.

In October, 1941, we first carried out this procedure at the Interstate Clinic. Since that time thirty additional cases have been done at the University of Minnesota Hospitals and at the Interstate Clinic. A description of the technique introduced by Kubik and Hampton for the injection and removal of oil from the subarachnoid space is as follows: The patient is placed face down on a tilt-type fluoroscopic table. The site for the introduction of the spinal puncture needle is located by fluoroscopic examination and the point for the puncture marked on the patient's skin. The optimal site for the puncture is L-3 when the lesion is at L-4 or L-5. However, if the lesion is suspected to be at L-3 or higher the puncture should be done at L-4. The field is prepared in the usual manner for a spinal puncture. A sterile circumcision sheet has been found to be the most convenient type of drape. A sterile towel used as a flap is fastened to the drape to protect the operative field during the fluoros-

From the Interstate Clinic (Juers), Red Wing, Minnesota, and the Department of Radiology (Peterson), University of Minnesota, Minneapolis, Minnesota.

copy. The drape is held in position by taping it to the shoulders. This procedure keeps the drape from slipping out of position when the patient is tilted and no difficulty is encountered in keeping the field immediately around the spinal needle

same syringe which was used for injecting the oil is preferable because the plunger and the barrel are well lubricated. This allows for easy manipulation without which *gentle* aspiration cannot be carried out. There is also less likeli-

Fig. 1. *a*, Iodized oil filling the end of the normal spinal subarachnoid space. sterile. An 18-gauge spinal puncture needle with a blunt point is carefully introduced and its position checked fluoroscopically to make certain that it is in the center of the spinal canal. The exact position of the needle has been found to be of the utmost importance for the successful removal of Lipiodol. Our poor results have occurred when the needle has not been centrally placed. The initial puncture should be very carefully done so as to avoid multiple punctures as this also causes poor results. When the needle has been properly placed 4 cubic centimeters of spinal fluid is removed and 4 cubic centimeters of Lipiodol is injected. The spinal puncture needle is left in position and covered with the sterile towel previously mentioned. The fluoroscopic examination is then carried out. One should be very careful not to jar the spinal puncture needle with the fluoroscopic screen. Spot films are made at any desired level by holding the film on the patient's back, above the needle, and making the exposure with the fluoroscopic tube. If desired, oblique and even lateral views can be taken by carefully rotating the patient into these positions. When the fluoroscopic and radiographic examinations have been completed, the oil is returned to the site of the spinal puncture needle. The sterile towel is folded back. The same 5 cubic centimeter syringe used for injecting the oil is attached to the needle and by extremely *gentle* traction on the plunger the oil is aspirated. The

Fig. 2. *a*, Arrow points to slight indentation produced by herniated disc. *b*, Almost all of the oil has been removed. *c*, Final result showing a few tiny droplets remaining.

hood of air leaking in around the plunger. If the patient complains of pain during the aspiration it usually means that a nerve root has been pulled up to the end of the needle. The suction should be stopped momentarily and the needle rotated slightly to overcome this difficulty. The aspiration is continued until spinal fluid appears. The needle is again covered with the previously mentioned sterile flap. The amount and location of the remaining oil is determined fluoroscopically and the position of the patient is changed if necessary, chiefly by tilting the table, in order to collect the oil around the tip of the needle again. Aspiration is repeated until clear spinal fluid again appears. Fluoroscopy and aspiration are repeated alternately until all the oil has been evacuated. In order to obtain the last few droplets of iodized oil it may be necessary to suck out a few cubic centimeters of spinal fluid. Including the 3 or 4 cubic centimeters of spinal fluid initially removed for laboratory examination it is not necessary to take out more than ten cubic centimeters for the entire procedure.

In our first cases we were not always successful in removing all of the oil. This was due to lack of appreciation of the importance of the points mentioned above. In the last twenty-four cases we have had uniformly good results.

Fig. 3 *a*, Arrow points to ruptured disc at the lumbosacral junction. *b*, Arrow points to needle in perfect position between spinous processes of the 2nd and 3rd lumbar vertebrae. All the oil has been removed. *c*, A few tiny droplets of oil are visible after the needle is withdrawn.

Fig. 5 *a*, Small indentation at the 5th lumbar vertebra on the left produced by a ruptured disc which was found at operation mostly lateral to the dural sac. *b*, All but a few tiny droplets have been removed. The needle is in excellent position.

Summary

Kubic and Hampton have reported a new method for the aspiration of iodized oil from the spinal subarachnoid space. This consists of as-

pirating the oil through the same spinal puncture needle through which it was injected. We have used this method successfully in thirteen out of seventeen cases. Although the procedure is basically very simple there are several points in the

Fig. 4 *a*, Ruptured disc present between the 4th and 5th lumbar vertebrae on the right. *b*, Needle slightly to right of midline. All oil removed. *c*, Final film after removing needle.

technique which are essential for a successful aspiration. These are as follows:

1. The site for the puncture is best determined fluoroscopically.
2. The needle must enter the dural sac as close to the midline as possible. This position should be checked fluoroscopically before the oil is injected.
3. Multiple punctures must be avoided.
4. Very gentle suction using a small syringe (2-5 c.c.) is necessary to avoid sucking a nerve root or piece of membrane into the end of the needle.

THE REMOVAL OF IODIZED OIL (LIPIODOL) FROM THE SPINAL CANAL AFTER ROENTGEN DIAGNOSIS

GORDON R. KAMMAN, M.D., F.A.C.P., and JOHN P. MEDELMAN, M.D.
Saint Paul, Minnesota

IODIZED poppy seed oil (lipiodol) still is considered the best contrast medium for roentgen diagnosis of intraspinal lesions. Although it has been in use for many years, and a large number of people are going about their daily tasks with several cubic centimeters of lipiodol floating around in their cranio-vertebral cavities, one cannot help but feel somewhat apprehensive about injecting a non-absorbable and potentially irritating substance into such an important space as that surrounding the central nervous system.

Nor is this apprehension entirely without foundation in clinical experience. Maclaire² reports one case in which lipiodol became encysted at the site of a lesion previously exposed by laminectomy and caused an unmistakable meningomyelitis. In spite of the fact that the oil was evacuated from these cysts at a second operation the cord damage was irreversible and the patient grew progressively worse and was totally disabled at the time of the report. Maclaire refers to his experience in this case as "horrible," and concludes that lipiodol should be used only as a last resort, and should be entirely restricted to those cases where laminectomy is to be performed within a few days, at which time oil can be liberated from the canal. Walsh and Love⁴ defend the intraspinal use of iodized oil by saying that examination of the cerebrospinal fluid from twenty-four patients who had had intraspinal injections of lipiodol failed to show any clinical reactions that might not have been produced by a spinal or cisternal puncture with the withdrawal of cerebrospinal fluid alone. However, they do say that the injection of iodized oil into the subarachnoid space in certain cases in which partial or complete obstruction of the circulation of the cerebrospinal fluid exists, might accentuate clinical symptoms. Craig¹ feels that intraspinal inflammatory processes might be irritated by iodized oil. This view is supported by the experience of one of us (G.R.K.) who some years ago had the unfortunate experience of causing an acute exacerbation of symptoms in a patient who was given lipiodol because a cord tumor was suspected when she was in reality suffering from multiple sclerosis. This patient became perma-

nently disabled and letters received from her for several years afterward were vituperative to say the least. Oldberg³ states, "Anyone who has had perforce to dig about in the soggy mess which is the cauda equina of some unfortunate in whom 5 or 10 cubic centimeters of lipiodol had been optimistically injected a year or two previously will understand" that indiscriminate use of the substance in many sporadic cases where it is not indicated is harmful.

With these experiences in mind, it was welcome news when one of us (J.P.M.) learned from Dr. Aubrey O. Hampton, of the Department of Roentgenology of the Massachusetts General Hospital, of a method for overcoming the main objection to the use of lipiodol. He read a paper, as yet unpublished, describing the method for lipiodol removal, at the 1941 meeting of the American Roentgen Ray Society and the credit for introduction of the method belongs to Doctor Hampton and his associates. The objections to the use of lipiodol have been bound up in the fact that its removal has heretofore been considered impossible without opening the dural sac at operation and that, even in those cases which were operated upon, a large percentage of the material remained after an attempt at removal during surgery. A description of the method of removal as we have employed it, follows:

The entire procedure is carried out on the fluoroscopic table which must be equipped with a change-over switch to radiographic current so that films may be obtained during the examination for a permanent record of the findings. The patient is placed prone on the table and a preliminary fluoroscopy is done to locate the spinous process of the third lumbar vertebra. This is marked on the skin so that the lumbar puncture can be made at the interspace directly below. The lumbar puncture is then done at this level with the patient remaining prone. The level is important because in the average patient the maximum curve of the lumbar lordosis will cause the lipiodol to collect in the area when the patient is placed approximately horizontal. A 16 or 18 gauge needle is used. This should have as short a bevel as can be used for the purpose. It is

very important that the puncture be made in the midline and that the course of the needle does not deviate to either side. The roentgenologist can be of assistance in this regard by sighting

one has the advantage of visualizing by fluoroscopy the position of the mass of oil in relation to the tip of the needle in one projection as frequently as necessary but, even so, removal of the

Fig. 1. Roentgenogram showing the amount of the oil injected and also the defect at the third lumbar interspace.

Fig. 2. Roentgenogram showing the amount of lipiodol remaining after aspiration. Note the presence of the needle which is not removed during the examination.

The quality of the roentgenograms is poor because they are made without a Bucky diaphragm.

from the foot of the table which is a more advantageous position for determining the direction of the puncture than is the operator's position directly above the patient. The normal pressure will cause the spinal fluid to flow through the needle when the dural sac is entered and fluid can be withdrawn into a syringe for laboratory procedures. The lipiodol is then injected. We use 4.5 c.c. Many workers use less but we feel that the larger amount is more satisfactory and cannot be objected to as long as it is to be removed later. The usual diagnostic procedures are then done with the spinal puncture needle being left in place.

After the necessary study of the dural sac, the lipiodol is removed. This is apt to be a tedious procedure. The patient is left in the prone position. A syringe is attached to the puncture needle. It is important that this syringe be small. One of 2 c.c. capacity is most satisfactory. Of course

oil is difficult. The puncture needle must be held firmly between the thumb and forefinger of the operator's hands with the rest of the hand braced against the patient's body. A slow and steady pull by the other hand on the barrel of the syringe gives best results, using as gentle a pull as can possibly be used in causing the rather heavy oil to flow through the needle. Great force should not be used. At the beginning of the removal a fair flow of oil may be obtained. Later its flow is apt to be intermittent. This may be due to blocking of the tip of the needle by a nerve root. It may also be due to an improper level of the tip of the needle in relation to the oil in which case spinal fluid only is withdrawn. The level of the tip of the needle may then be slightly changed. If this does not bring about a return of the flow of oil it frequently helps to move the mass of oil away from the needle by tilting the patient and then to bring it back by returning the patient to

the horizontal position. These maneuvers must be employed several times during the course of the removal of the oil.

Practically all of the lipiodol can be withdrawn by patient effort. A drop or two will always remain but the portion left is so small in amount that there can be no objection to its presence in the dural sac.

The following case report illustrates the working of this method:

J. W. was referred to one of us (G. R. K.) by Dr. J. W. Edwards of St. Paul, on March 5, 1941. The family and past histories were negative as far as Mr. W.'s present complaint was concerned, and there was no history of injury. About November 1, 1940, the patient began to notice a "soreness" down the left sciatic distribution. This was aggravated by activity and by January, 1941, Mr. W. was barely able to walk or to sit down. In March the positive neurological findings consisted of pain on left straight leg raising and impairment of touch and pain sense over both lower lumbar and first sacral dermatomes. Roentgenograms of the spine and pelvis were negative and the cerebrospinal fluid was normal with respect to dynamics, cell count, colloidal gold curve, total protein, and Wassermann reaction. The left sciatic pain persisted so that on March 22, 1941, air myelography was carried out. The findings were equivocal and the final diagnosis of Dr. Harold O. Peterson, roentgenologist, was "Possible lesion at the lumbrosacral junction such as a herniated disc, but a final conclusive diagnosis should not be made from these findings. The remainder of the lumbar canal is probably normal." Because of the persistence of symptoms and signs together with the suggestive x-ray findings, surgery was decided upon. Accordingly on April 5, 1941, Dr. Wallace P. Ritchie performed a partial laminectomy on the fifth lumbar vertebra and found a thickened ligamentum flavum. Beneath this a protruded intervertebral disc was found between the bodies of the fifth lumbar and first sacral vertebrae. This was removed. The patient made an uneventful recovery from the operation and was discharged twelve days afterward.

The next time Mr. W. was seen was on December 3, 1941, at which time he stated that eight weeks pre-

viously he had suffered a slight wrench to his back following which he experienced a burning sensation in the calf of his left leg. This was aggravated by motion and had grown progressively worse until the patient was forced to go to bed. The neurological examination was entirely negative but it was felt that a roentgen examination of the spinal subarachnoid space should be made. Because the air myelogram in March had been so inconclusive, it was feared that because there had been previous surgery the same contrast medium would give still less satisfactory information, and the lipiodol technique described above was decided upon.

There was definite evidence of a space taking lesion in the spinal canal at the level of the disc between the third and fourth lumbar vertebrae. Following the taking of spot films, the lipiodol was removed through the spinal needle, all of the oil being withdrawn except for a very small globule.

On December 10, 1941, Doctor Ritchie removed the laminae of the third and fourth lumbar vertebrae on the left side. No evidence of a protruded disc could be found, but the ligamentum flavum was extremely large so it was removed. Following the operation, Mr. W. made an uneventful recovery and left the hospital on January 10, 1942, greatly relieved of his pain but still having some discomfort in the posterior aspect of his left thigh.

Conclusions

1. Iodized poppy seed oil (lipiodol) when injected into the subarachnoid space and allowed to remain there indefinitely is a potentially harmful substance.
2. A method is described by which the substance can be removed from the spinal canal immediately after roentgenograms are made.

NOISE TO PLEASE ONESELF

"One makes noise to please oneself and language to please mothers and, later, neighbors."

This sums up the child's own feeling about a conflict which makes some children stutter, in the opinion of Dr. John A. Rose, of the Winston-Salem, N. C., Child Guidance Clinic and the Bowman Gray Medical School.

Primary function of speech is self-expression. Imposed on this is the function of communication. When families and their social group place much emphasis on this second function of speech, perhaps hero-worshipping political and religious orators, the child may either struggle against this attitude and become a stutterer or he may take on the family attitude and become a "verbalist."

Fundamentally, stuttering and other speech disorders like feeding and school problems, arise from a "troubled child-parent relationship."

The child guidance clinic, working as it does with both child and parents, therefore has a chance, Dr. Rose believes, even with its limited time, to help with the speech difficulty.—*Science News Letter*, February 28, 1942.

BOILED LIVER EXTRACT IN TREATMENT OF ACNE VULGARIS

C. A. BOREEN, M.D.
Minneapolis, Minnesota

IN March, 1940, Wallace¹ made a preliminary report on the use of subcutaneous injections of boiled liver extract in the treatment of acne vulgaris. The active ingredient was supposed to be a specific skin factor which he called factor S. However, the number of cases treated was small. He states the treatment was fairly successful.

During the fall and winter of 1940 and 1941 I had the opportunity of treating a series of cases at the Students' Health Service of the University of Minnesota. The number of students treated was fifty. There were nineteen females and thirty-one males. The average age was nineteen. The cases were selected at random, and they varied from mild to severe pustular acne.

The liver extract was obtained from a pharmaceutical house and boiled for thirty minutes. The extract was supplied in 5 c.c. ampules and each patient was treated from his individual ampule. The dose recommended was 0.4 c.c. This dose was given twice a week for six weeks, and the results were tabulated at that time as follows: twenty patients showed no improvement; twenty-three showed slight improvement; and in seven there was marked improvement.

The fifty students were given a similar course of treatment with liver extract obtained from another pharmaceutical house, but the dosage was 0.8 c.c. twice a week. The results at the end of this series of injections was the same as in the first course of treatment. Those who showed no improvement after the first course of treatment showed no improvement after the second. Those who showed slight improvement continued to improve slightly and those who showed marked improvement continued to improve slightly.

The average number of injections given for both series was twenty. In the second series some of the students did not receive the twelve injections prescribed.

The only other treatment given during the course of treatment was the local application of a mild astringent solution.

Those who showed considerable improvement

were all of the mild type of acne. The improvement probably can be ascribed to the astringent solution used plus some tonic effect of the liver extract rather than a specific skin factor S.

One patient (Case 4), with no improvement with liver extract, was given six x-ray treatments. The dosage at each treatment was eighty Roentgens and was given once a week. There was considerable improvement. Another (Case 7) had received twenty x-ray treatments in Honolulu over a period of two years. The dosage was not known but must have been rather small. Naturally we did not give any more x-ray. A course of liver extract was given with no appreciable effect. She did say that the x-ray had helped her considerably. Another (Case 15) showed no improvement with liver extract but considerable improvement after six x-ray treatments. In Case 22 there was no improvement with liver extract but marked improvement after four x-ray treatments.

One patient (Case 25) had a constitutional reaction from the injections. She became nauseated after each treatment and the injections were stopped after the sixth treatment. There was a slight improvement. She was then given x-ray treatments. She received only three, but there was considerable improvement.

Summary

Fifty patients with acne vulgaris of varying degree were treated with subcutaneous injections of boiled liver extract. Twenty showed no improvement; twenty-three improved slightly; and seven improved considerably. The few who were later treated with x-ray showed considerable improvement.

Conclusions

1. The treatment with boiled liver extract has been disappointing.
2. When local treatment fails, x-ray therapy should be instituted.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

Frank C. Andrus, Pathologist

Presentation of Case

DR. THOMAS A. PEPPARD: The case is that of a fifty-three-year-old white female office worker whom I saw in consultation with a physician on September 8, 1941, and subsequently. The family history is not pertinent. The patient stated that she had been told by her mother that as an infant her mother, while holding her in her arms against her chest, could feel the baby's heart pounding. As a child she could not indulge in the usual activities with the other children but was forced to sit at one side and watch them play. She had had mumps, catarrhal jaundice, and influenza. She had had no operations. Her menopause had occurred at the age of fifty-two years. She had been employed for many years as an office worker and could carry on that job without any inconvenience. On or about August 27, 1941, she had her beginning symptoms which included occipital headaches, nausea, and vomiting. Later she felt weak and found that she had a fever, her temperature being 103 degrees. She had no chest or abdominal pains. Her weight upon admission was 150 pounds and she had maintained that weight for some time. There was no considerable expectoration or chronic cough. She was admitted to a private hospital with a fever of 102.4 degrees, pulse 112 per minute, and respirations 24 per minute. A tentative diagnosis of pneumonia was made.

Laboratory Data.—The specific gravity of the urine varied between 1.002 and 1.018; it was negative for albumin on some occasions and on other determinations showed a trace. There were no casts or red blood cells at any time. The hemoglobin was 80 per cent on September 2, 1941. The leukocyte count was 11,500 on admission but subsequently dropped to 7,800 and 8,600. On October 10, 1941, a month after admission, the hemoglobin dropped to 74 per cent. She raised some sputum which upon examination showed many organisms, mostly streptococci. Agglutination tests were done but were negative. An x-ray plate taken on September 11, 1941, showed a slight degree of cardiac enlargement with a generalized increase in bronchovascular markings in both lungs with scattered areas of infiltration. She was given sulfonamide drugs in addition to supportive therapy without any appreciable change in her condition. Her temperature ranged between 99 and 100 degrees in the mornings and to about 102 degrees in the evenings; it continued at those levels throughout her hospital stay.

I saw her on October 8 and October 15. She was breathing with some apparent respiratory effort although she stated that she was not short of breath.

There was slight general cyanosis. Careful search revealed no petechiæ on the skin or mucous membranes at any time. There was no adenopathy. The radial pulse dropped back quickly, more so when the arm was raised. Pulsation was felt in the fingertips and capillary pulsation was noted in the fingernails. There was no clubbing of the fingers or toes. There was normal pulsation in the femoral and dorsalis pedis arteries. A systolic sound was heard over the femoral artery but it was not "pistol-shot." No Duroziez murmur was heard. There was no subcutaneous edema. The blood pressure in the arm was 140/65 and in the leg 170/96. The blood pressure on admission had been 154/70. The heart appeared to be slightly larger than normal. A systolic thrill was felt in the second left interspace, more noticeable on expiration. There was normal sinus rhythm. In the first, second, and third interspaces, but more especially in the second, the normal heart tones were largely replaced by a rather harsh, blowing continuous murmur. This murmur was transmitted downward over the sternum. The lungs were resonant anteriorly and posteriorly except for a small area in the region of the right hilus. There were no pleural rubs or any evidence of fluid in the pleuræ. The breath tones were vesicular throughout. At both bases posteriorly, more numerous and extensive in the right base, fine moist rales were heard. There was normal transmission of whispered and spoken voice sounds. The liver was palpable but was not considered to be enlarged. The spleen was enlarged, readily palpable, but not tender. There was no abdominal rigidity, no masses, and no tenderness.

My diagnosis was patent ductus arteriosus with subacute bacterial endocarditis. There were no evidences, however, of embolic phenomena at any time during her stay. I considered that it might have been possible that she had some pulmonary emboli at the time of onset. She had a reasonably good appetite and a sense of well being not common to patients with bacterial endocarditis. She did not develop any anemia as rapidly as such patients often do. A blood culture taken on November 6 revealed a growth with characteristics of *Streptococcus viridans*. The patient was discharged from the private hospital on November 2, 1941.

DR. H. PERLMAN: Following her discharge from the private hospital, she went to a rest home. Three weeks before admission to the Minneapolis General Hospital, she developed dyspnea, orthopnea, and swelling of the legs. She was admitted to this hospital on January 22,

1942. Physical examination on admission revealed a generalized pallor. She was moderately dyspneic and orthopneic. Rales could be heard at both bases of the lungs. The other physical findings were the same as observed previously by Dr. Peppard. The blood pressure at this time was 128/46. A fluid wave and shifting dullness could be exhibited over the abdomen. The liver was palpable 3 cm. below the right costal margin. The spleen was again palpable. There was a three plus pitting edema of the feet and ankles. Slight cyanosis of the fingernails was noted. The venous pressure was 10 cm. of citrate solution. There was no evidence of petechiae at this time.

Laboratory Data.—The hemoglobin was now 55 per cent, the erythrocyte count 2,800,000, leukocyte count 3,800, and the differential count 82 per cent neutrophils, 14 per cent lymphocytes, and 4 per cent monocytes. The urine had a specific gravity of 1.014; it contained a trace of albumin, no sugar, no hyaline casts, 3 to 5 granular casts, and numerous red and white cells. An electrocardiographic tracing showed left axis deviation, slurring of the QRS complexes in all leads, and slight depression of STs. Repeated urine examination revealed from a trace to two plus albumin. The blood urea nitrogen was 28 mg. per cent. The phenolsulphonephthalein excretion test showed a total of 19 per cent in two hours. A blood culture showed *Streptococcus viridans*.

The patient was put on a cardiac regime with limited fluids. She was digitalized and responded nicely. A few days after admission all evidence of decompensation was gone. On January 29 fresh petechial hemorrhages were noted in the conjunctiva of the left eye. The patient was given repeated blood transfusions which raised her hemoglobin to 89 per cent. The erythrocyte count was 4,780,000 and the leukocyte count 13,400. She was given sulfathiazole which had to be discontinued after five days because she complained of nausea and vomiting. The blood urea nitrogen on the 12th hospital day had risen to 35.7 mg. per cent. Her entire course in the hospital was afebrile. Ligation of the ductus was suggested so the patient was transferred to the surgical service on February 5, 1942. Intratracheal administration of cyclopropane was started. The patient stopped breathing after twenty minutes of anesthesia and before any operative procedure could be carried out.

Clinical Diagnoses.—(1) Patent ductus arteriosus; (2) Subacute bacterial endocarditis.
(Roentgenogram shown.)

DR. E. T. BELL: Would you say there was any hypertrophy of the right heart?

DR. OLSON: This is the only film taken and shows only left enlargement.

DR. BELL: You do not see anything there that you could interpret as a dilated pulmonary artery?

DR. OLSON: The vessels seem to be enlarged and there is congestion in both bases.

Autopsy Findings

DR. R. PAPERMASTER: At the time of autopsy no petechial hemorrhages were noted upon careful examination. The heart weighed 490 grams. This weight included the great vessels as we wanted to keep the specimen intact. There was hypertrophy of the left ventricle. There was a patent ductus arteriosus measuring 12 mm. in its external diameter. It arose just beyond the left subclavian artery. There was a semilunar fold just proximal to the external orifice of the ductus arteriosus projecting 6 mm. into the lumen of the aorta. This fold included one-third of the circumference of the aorta. The internal diameter of the ductus arteriosus was 3 mm. in its contracted state. The right auricle and ventricle were not dilated. The tricuspid and pulmonary valves were normal. The root of the pulmonary artery measured 95 mm. in circumference (normal 70 mm.). A patch of vegetations 2 cm. in diameter were present in the conus 1 to 3 cm. above the pulmonary valve. The vegetations were also found surrounding the pulmonary orifice of the ductus arteriosus. The internal pulmonary orifice of the ductus was 3 mm. in diameter. Two recent vegetations were also seen on the medial leaflet of the mitral valve.

There were two infarcts in the lower lobe of the left lung. The spleen weighed 520 grams and showed septic splenitis. The liver weight 1,720 grams and showed evidence of a long standing chronic passive congestion. The kidneys were normal grossly. The remainder of the examination showed nothing of note.

DR. ANDRUS: Microscopic sections of the myocardium show an extensive acute exudative myocarditis with small abscesses and necrosis of muscle fibers. The lesions on the mitral valve and in the pulmonary artery are characteristic vegetations of subacute bacterial endocarditis. The tufts of some of the glomerular capillaries were thrombosed giving the "focal" or "embolic" nephritis so often found in cases of bacterial endocarditis. The pulmonary infarcts had gone on to abscess formation.

Anatomic Diagnoses.—(1) Patent ductus arteriosus; (2) Subacute bacterial endocarditis; (3) Exudative myocarditis; (4) Focal or embolic glomerulonephritis; (6) Myocardial insufficiency; (6) Pulmonary infarction and abscesses.

DR. BELL: This is marked dilatation of the pulmonary artery. I don't know why there was hypertrophy of the left ventricle and not of the right. This is the picture of an arteriovenous aneurysm. That is why the left heart is hypertrophied and why the pulmonary artery is dilated. I should think that the pressure in the pulmonary artery would be increased.

DR. M. SHAPIRO: Practically all of the cases that have been reported show that young people have hypertrophy of both right and left ventricles. This is the only one I have seen that had left axis deviation.

DR. BELL: The right ventricle is not dilated; but you can't understand why the right side is not hypertrophied when it must work against increased pulmonary pressure.

DR. SHAPIRO: How long was the ductus?

DR. ANDRUS: The two vessels were in apposition.

DR. BELL: That is the way they usually are.

DR. ANDRUS: How large is this opening in most cases?

DR. BELL: A pretty fair size opening—3 mm. That makes quite a leak. But it isn't evidently the most severe type because this woman was 53 years old and her trouble was from endocarditis more than from the cardiac anomaly.

DR. SHAPIRO: Whenever a new thing like this operation comes out, we are inclined to rush in and try to help these patients. Among the men who have studied this condition, it is the opinion that this operation should be done in children as young as possible but then only if they are beginning to show signs of beginning cardiac disability. Jones had a number of patients in whom the heart size and the blood pressure returned to normal.

Summary

DR. PAPERMASTER: This condition occurs twice as often in females as in males. In Abbott's series of 150 cases, it was found associated with other congenital defects in two-thirds of the cases. In the ninety-two cases with patent ductus arteriosus as the only cardiac anomaly, the maximum age was sixty-six years, the average age at death twenty-four years. This included twenty cases who died in infancy. The patent ductus arteriosus represents a persistence of the left sixth aortic arch. In some cases, when associated with certain other cardiac anomalies, it acts as a compensatory mechanism to maintain life.

It is generally assumed that a continuous leakage takes place from the aorta to the pulmonary artery (arteriovenous shunt) because the pressure is high in the aorta. This pressure relationship is maintained until some respiratory obstruction sets in, as prolonged crying or coughing, when the pressure in the pulmonary artery becomes greater, a venous-arterial shunt occurs and there is a transient cyanosis. The fact that the pulmonary artery is practically always dilated, and the left ventricle is usually hypertrophied, more than the right, is evidence that the flow is usually arteriovenous. Also, in the infective process that supervenes, the pulmonary end of the ductus and adjacent tissues is always the initial seat of the vegetative inflammatory lesion suggesting that this is the site of strain of a continuous arteriovenous shunt. This leakage of blood from the high pressure aorta to the low pressure pulmonary artery results in a fall in peripheral diastolic pressure and a rise in pulmonary pressure. Subacute

bacterial endocarditis is relatively more common in patent ductus arteriosus than in other congenital heart lesions.

The diagnosis of patent ductus arteriosus is made by physical and x-ray findings. These patients show poor physical development. Physical findings typically consist of the so-called machinery murmur heard over the left upper chest anteriorly and a marked thrill over the same area. However, the murmurs and thrills may be absent if the ductus is very large. Maude Abbott states that only about one-third of the cases have the typical murmur. There may be only a systolic murmur, especially in children. Enlargement of the pulmonary artery to percussion may be demonstrated. Absence of cyanosis in the presence of these other findings is an important diagnostic feature. The systolic pressure is normal and the diastolic pressure is low in typical cases. Peripheral signs of aortic regurgitation may be found.

Treatment of patent ductus arteriosus has been limited to the usual treatment of its complications, especially heart failure and bacterial endocarditis. A new treatment has recently been described, namely, ligation of the ductus. Gross has reported thirteen cases of successful ligation of the patent ductus arteriosus. One case died two weeks postoperatively due to *Staphylococcus aureus* infection. Only one other case derived no benefit from the procedure. Gross noted the following benefits in his cases: (1) the thrill ceased; (2) the diastolic pressure rose but the systolic pressure remained normal; (3) the activity and excursion of the heart decreased; (4) growth and development improved; (5) dilatation decreased but hypertrophied hearts did not change; however, the cardiothoracic ratios approached normal in one and one-half to two years postoperatively; (6) those who had had episodes of orthopnea, dyspnea, and cyanosis no longer had them; (7) there was a subjective and objective increase in ability for physical activity. Jones, Dolley, and Bullock reported thirteen cases successfully ligated. One of these died of subacute bacterial endocarditis. The possibility of treating bacterial endocarditis in cases with patent ductus by ligation has also been advanced. The first case of subacute bacterial endocarditis cured by ligation was reported in 1940 by Tour-off and Vasell. In this patient the ductus was divided and doubly ligated. The blood became sterile and the patient was reported to be living and well thirty-six weeks after operation. These workers also report three other similar cases, two died of hemorrhage at the time of operation, one died thirty-two weeks postoperatively of bacterial endocarditis.

CASE REPORT

ESOPHAGEAL PERFORATION FROM A STOMACH TUBE

JAMES M. HAYES, M.D.

Minneapolis, Minnesota

PERFORATIONS of the esophagus have been reported quite frequently but so far as I know perforation of the esophagus by means of a soft rubber stomach tube has not been reported.

severe immediately. Emphysema may develop rapidly. The patient becomes very ill almost at once, and evidence of shock comes on early. Fever and leukocytosis develop early.

The extension of infection from the perforation into the mediastinum is the dangerous factor. The arrangement of the facial planes in the neck is an interesting study as related to the extension of the infection into the mediastinum. I shall not, however, attempt a discussion of these planes in this paper. Pearse has well described the anatomy of these planes. From his discussion it would seem that a perforation of the esophagus on the anterior or lateral surface would be less likely to result in the extension of the infection to the mediastinum than in the case of a posterior perforation. According to Pearse the retrovisceral space is the most important highway of communication between the neck and chest. Perforation of the thin posterior wall of the cervical esophagus brings the retrovisceral space in contact with infection. This in turn is in direct communication with the posterior mediastinum, one of the most dangerous areas in the human body for acute infection to lodge. When this takes place, without time for a walling off process to take place, a surgical emergency exists in which time is an important element.

Case Report

Mrs. R. O., aged 53, was normal physically up to the time of this accident. About 6 p.m. she was eating a chicken dinner at home. Suddenly something lodged in her throat, and she became quite desperate. Her daughter ran to the phone and called a doctor living close by. The daughter was very much excited and told the doctor to come in a hurry, that her mother was "choking." He picked up a soft rubber stomach tube and rushed over to the house immediately. When he arrived the mother seemed in desperate condition. She was cyanotic, apparently not breathing and in marked collapse. He immediately attempted to pass the stomach tube, hoping to dislodge the material in the esophagus. She did breathe better for a short time, but the pain was intense so she was rushed to Asbury Hospital where Dr. Boies was called and passed the esophagoscope. He extracted a small piece of bone from the upper esophagus. At the same time he observed a perforation in the posterior left area of the esophagus. She continued to have severe pain, dyspnea and dysphagia, and the following day a marked emphysema developed in the left side of the neck and out over the left shoulder.

I saw her about noon on the following day and operation was begun about 2 p.m. that same day.

Operation.—An incision was made in the left side of the neck along the lower medial border of the sternocleidomastoid muscle. This muscle was then retracted,

(Continued on Page 306)

Fig. 1. Structures involved in operative procedure.

Perforations of the esophagus are usually classified under three main types:

1. Slowly perforating, or erosion by a foreign body lodged in the esophagus.
2. Minute perforations, such as those made by pins, fishbones and the like.
3. Gross, immediate perforations produced by instrumentation or tearing of the wall during removal of a sharp body.

In the first two, an inflammatory process may be set up that produces a protective mechanism that prevents the extension of the infection into the posterior mediastinum.

The third is the most serious and the resulting signs and symptoms are the most pronounced. Local pain and that radiating into the chest and shoulder is usually

Reported before the Minneapolis Surgical Society May 1, 1941.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF THE MINNESOTA STATE MEDICAL SOCIETY

By ARTHUR S. HAMILTON, M.D.

Minneapolis, Minnesota

(Continued from March issue.)

Third Semi-Annual Meeting

The third semi-annual meeting of the State Medical Society was held at Minneapolis, June 13 and 14, 1871, in the Pythian Hall, with fifty-four members present. A letter of regret at his inability to be present was read from Dr. Samuel Willey, whose health had required his removal to Bayfield, Wisconsin, and a committee was appointed to send greetings to him.

Drs. A. E. Ames and N. B. Hill, delegates from the Minnesota State Medical Society, reported the meeting of the American Medical Association at San Francisco. The two interesting items in their report were the comment on Dr. Hewitt's paper on "Climatology of Minnesota," which had been very favorably received, and the action on the reception of delegates to the American Medical Association from "female colleges" already discussed.

Those elected to membership at this meeting are listed at the end of the volume. Dr. A. A. Ames, of San Francisco, was elected an honorary member.

Later it was agreed to extend the annual meeting from two to three days, but there is no evidence that the change was actually made effective at the next meeting.

Dr. Brewer Mattocks of Saint Paul, as essayist for the meeting, read a paper on "Diseases of Children." Dr. Mattocks said in his paper that the nature and treatment of diseases of children was the same in principle as in the diseases of adults; that the matter of children's diseases was not a specialty in the profession and that children were governed by the same laws of being as adults. His views were sharply contradicted by Dr. Hewitt, of Red Wing, who took the ground that the child was an imperfect immature being, whose pathologic conditions were essentially distinct from those of human maturity.

A very elaborate dinner was served to the members by Dr. and Mrs. A. E. Ames at their new home at Fourth and Ames Streets on the evening of June 13. The doctor's grounds were exceptionally beautiful and the banquet included everything good to eat but the next morning's *Tribune* informs us that dancing, cards and wine were tabooed.

On the following morning, and after much discussion and considerable opposition, Dr. Stone's bill legalizing dissection, to be presented to the next Legislature, was adopted.

Dr. W. W. Mayo reported a case of rectocele of fourteen years' duration which was finally cured, and Dr. C. G. Goodrich reported a case of ovarian cyst in a child of eight years.

Dr. Stone, as editor of the *Northwestern Medical and Surgical Journal*, referred to the articles of Mattocks, Mayo and Goodrich as the most noticeable features of the meeting. All appear in the Transactions for 1872, and Dr.

Mayo's report is also found in the *Northwestern Medical and Surgical Journal*, Vol. II, No. 1.

In an editorial of July, 1871, in his *Journal*, Dr. Stone urged that all regular physicians join the State Society and, to make this effective, he advised that a law be passed forbidding members of the Society to consult with anyone not also a member of the Society.

Fourth Annual Meeting

The fourth annual meeting of the Minnesota State Medical Society was held in the United States Court Rooms in Saint Paul, on February 6 and 7, 1872. Dr. Franklin Staples presided and seventy members were present.

New members were elected and later in the meeting Dr. A. E. Ames introduced Professor Thayer, formerly of Vermont, who appears to have been connected with the Northern Pacific Railway. He was cordially received and elected an honorary member.

It was again reported that no essays had been received in the contest for the prizes offered.

Dr. A. B. Stuart, from the special Committee on Legislation, reported a memorial and Bill to establish a State Board of Health, which was accepted and ordered printed.

For some years past it had been the custom for Iowa, Wisconsin and Minnesota to appoint official representatives to each other's annual meeting. On this occasion, Dr. Marks was present from the Wisconsin State Society, probably the first official delegate to actually appear at a Minnesota State meeting.

Dr. Stone announced that the bill formerly known as the bill to legalize dissection but now more euphoniously known as the Anatomy Bill or the Bill to Promote the Science of Medicine and Surgery in the State of Minnesota had been laid before the legislature and would undoubtedly pass if it met with the *unanimous* approval of the Society, which unanimous approval was accordingly given.

In the course of preceding years a rather elaborate system of committees and delegates dealing with different phases of medicine had gradually grown up, and at this time included the following: Executive Committee; Finance Committee; Publication Committee; Committee on Ethics; Committee on Medical Societies; Board of Censors; Essayist for the Annual Meeting; Delegates to American Medical Association; Delegates to Wisconsin State Medical Society; Delegates to Iowa State Medical Society; Committee on Necrology; Committee on Epidemics, Climatology and Hygiene; Committee on Practical Medicine; Committee on Surgery; Committee on Obstetrics; Committee on Gynecology; Committee on Ophthalmology; Committee on Materia Medica; Committee on Medical Education; Committee on Medical Jurisprudence; Committee on Diseases of the Nervous System; Committee on Prize Essays.

Most of these committees from time to time made special reports, but that of Dr. Sweney's Committee on Epidemics, Climatology and Hygiene for this year, deserves special mention. It appears in the current transactions† and covers nearly sixteen pages. The Committee had sent out a questionnaire to all practitioners of the state in good standing, numbering about one hundred and fifty, but only eighteen responses were received. Goodhue County particularly distinguished itself, in that every regular practitioner save one answered.

In view of the elaborate observations reported from Dr. Sweney's committee,

†Trans. Minn. State Med. Soc., pp. 60-76, Feb. 6 and 7, 1872.

it is impossible to give any satisfactory abstract, but it should be stated that the findings cover a wide range of clinical conditions and deserve high commendation. They still make a distinction, though not clearly, between enteric or true typhoid on the one hand, and typhomalaria on the other. Clinical distinctions are discussed at considerable length but the wide difference in the type of cases reported from different localities make one feel that they did not all use the same terms with the same value. In not one instance are the anatomic features of typhoid invoked for diagnosis or even described. The general statement is made that enteric fever shows a decided decrease for the year and there is also a much less widespread appearance of the enteromalarial form. Paludal fevers have been more than usually prevalent though generally of a mild type and, whatever this paludal disease may have been, it certainly had many of the characteristics of enteric fever. Some localities reported remittent fever as much more prevalent than intermittent, while others state that the conditions are exactly the reverse.

The discussion as to the climate and phthisis still goes on. "Strumous" children frequently lose all trace of the disease, and "scrofula" is less frequent and less severe than in the East. Phthisis pulmonalis in its early stages is generally benefited but there is obviously a growing doubt that the late stages are in any way helped.

From the Committee on Surgery, Dr. Hewitt gave a very well prepared résumé of "The History and Rationale of the Antiseptic Treatment of Wounds," and the following is quoted from the report of the Committee on Surgery as showing the line of surgical thought:

The special topics proposed involved many important questions now under discussion by surgeons, e.g.: The Germ Theory of Disease; Antiseptic Treatment of Wounds; Kind and Form of Sutures; Use of Solutions, Oils, Unguents, Poultices, Glycerine, Alcohol, etc.; Frequency of Dressing; Effect of Diathesis, Position and Temperature and the Aids Available through the General System, as Iron, Opium, Ergot; Union by First Intention; Union by Second Intention; Management of Ulcers and the Use of Transplanted Skin; Counter Irritation as a Surgical Remedy.

Dr. Staples read his address on "Professional Ethics." He congratulated the Society on its progress. In its three years of existence it had gathered 143 members and had lost two by death. Dr. E. H. Smith, former secretary of the State Society, died of phthisis pulmonalis on February 12, 1871, and Dr. Perry Chance died at Delano on November 19, 1871. Four members of the Society had moved from the state during the year.

In his inaugural address on February 7, Dr. Mayo, the new president, paid his respects to the retiring president, Dr. Staples, and especially to the preceding officer, Dr. Samuel Willey, who appears to have been held in the very highest esteem by his fellow practitioners.

The Society was still eager to dispose of its prize essay fund and reported the following subjects for prize essays for the ensuing year:

1. *Phthisis Pulmonalis.*
2. *Rheumatism and Catarrh as Elements in Uterine Disease.*

Dr. Hewitt proposed the following amendments to the By-Laws governing the Society:

The general meetings of this Society shall be restricted to the morning sessions, and the afternoon and evening sessions shall be devoted to the hearing of reports and papers, and their consideration, in the following Sections:

1. Chemistry and Materia Medica.
2. Practical Medicine and Obstetrics.

3. Surgery and Anatomy.
4. Meteorology, Medical Topography, and Epidemic Diseases.
5. Medical Jurisprudence, Hygiene and Physiology.
6. Psychology.

The several sections mentioned above were to be held to a high level of scientific procedure, and no papers or reports were to be issued from the sections except such as might fairly be classed under the following heads:

- 1st. Such as may contain and establish *positively* new facts, modes of practice, or principles of real value.
- 2nd. Such as contain the results of well-devised original experimental researches.
- 3rd. Such as present so complete a review of the facts of any particular subject, as to enable the writer to deduce therefrom legitimate conclusions of importance."

Dr. Hewitt's motion was laid over until the next meeting and finally was not sustained, but the following, introduced by Dr. T. T. Mann, was adopted:

RESOLVED, That a committee of five be appointed to report at the annual meeting of 1874, upon the influences which the, external aspects of nature exert upon the imagination and understanding of man; and to what extent the physical organization is changed or modified by such influences.

The Committee on Medical Education made a somewhat lengthy report, but this will doubtless be covered in the Division of Medical Education.

A single sentence from the report of the Committee on Medical Jurisprudence shows that evils now complained of were well recognized in 1872: "The moral, intellectual and professional status of medical experts should be elevated."

The transactions for this meeting close with a copy of a proposed Act to establish a State Board of Health, and an Act to promote the Science of Medicine and Surgery in the State of Minnesota (the so-called Anatomical Act).

The Northwestern Medical and Surgical Journal,* a very short time later, announces the passage of the Anatomy Bill, legalizing dissection in Minnesota, and also the passage of the State Board of Health Bill. The Anatomy Bill passed the Senate by a vote of twenty-seven yeas to three nays, and the House by a vote of sixty-eight yeas to five nays. Dr. Stone gives special credit to Hon. D. M. Sabin of Stillwater for the successful passage of the bill.

The State Board of Health Bill also passed on March 4, 1872, after a severe and prolonged struggle and an apparent defeat, it being saved only by the action of the Committee, in whose hands it had been placed, cutting down the appropriation to five hundred dollars. Again it nearly met defeat at the hands of the Governor and Dr. Stewart is given credit by Dr. Stone, for its salvation.

The Board of Health Bill called for seven members, of whom five were appointed at the time—Drs. D. W. Hand, N. B. Hill, A. B. Stuart, C. N. Hewitt, and A. W. Daniels. Drs. Vespasian Smith, of Duluth, and G. D. Winch, of Blue Earth City, were added under announcement of June 11, 1872. The first meeting of the Board was held in the office of Dr. Hand, March 26, 1872. According to Dr. Hand, this was the third Board of Health to be established in the United States, Massachusetts having preceded us five years, and California two years. The Board organized by electing Dr. A. B. Stuart of Winona as president, and Dr. C. N. Hewitt of Red Wing as secretary, selections which could hardly have been better made in Minnesota at that time. Dr. Hewitt, in particular, had already met with national recognition in public health work.

Dr. Hewitt continued as secretary of the Board until 1897, a period of twenty-five years and during this time his work met the highest approval, both at home

*N. W. Med. and Surg. Jour., Vol. II, p. 384, Feb. and March, 1872.

and abroad. His first year's meager salary was \$200; for the following year it was \$500, and was gradually increased to \$2,500 in the year 1893. On January 11, 1897, Dr. Hewitt learned that he had not been reappointed to office. For this act there has been no official explanation though Dr. Folwell suggests that the probable explanation can be found in the Folwell papers. In his reports for 1895-1896 (p. 14), Dr. Hewitt wrote as follows: "The best of my life and effort have gone into this work. I have spared neither time, labor nor thought to make it what it ought to be. Such as it is, the record is made and closed."

The *Northwestern Lancet** contains an editorial on the failure of the Governor to reappoint Dr. C. N. Hewitt to the State Board of Health. As the *Lancet* puts it:

This has called forth a loud and indignant protest from the medical profession of the whole state, a protest to which has been joined the voice of those members of the laity who have been in a position to know of the excellence of Dr. Hewitt's work for the maintenance of the public health, and the unlikelihood that it will be possible to find another man for the position who will be as faithful, as industrious and as successful in the work as he. Twenty-five years ago, when Dr. Hewitt took office, in connection with the public health service, the science of preventive medicine as applied to communities was in its infancy. Except in the case of smallpox there was practically no such thing as quarantine against contagious disease, outside of that maintained at ports of entry against vessels from places where yellow fever or cholera existed. In Minnesota, attempts to control outbreaks of epidemic diseases had rarely been made, and had been feebly executed. The extent of territory to be covered was so vast, and in many parts so thinly settled, as to discourage the thought of providing it with efficient health service. Yet this was the very task which Dr. Hewitt undertook, and carried through so successfully that Minnesota is known more or less as a model state in this respect.

The Legislature of 1872, besides what appears already on the record, passed Acts to punish abortionists and attempts to procure abortion; an Act to require all incorporated villages, cities and towns to establish a local board of health; an Act to appropriate \$100,000 to complete the Minnesota Hospital for the Insane; and an Act allowing a physician, called to make a professional postmortem examination, \$6.00 a day and 10 cents per mile for mileage.

Fourth Semi-Annual Meeting

The fourth semi-annual meeting of the Minnesota State Medical Society was held at Rochester, June 11 and 12, 1872, with Dr. W. W. Mayo in the chair, and thirty members present. The minutes of the meeting are rather limited, though the *Northwestern Medical and Surgical Journal* describes it as one of the most pleasant meetings of the Society on record. It is stated that "harmony and good feeling prevailed; none of the much-vexed questions of ethics arose."

The *Northwestern Medical and Surgical Journal* for December, 1872,† contains a review of Dr. Hewitt's report to the American Medical Association on the "Climatology and Epidemics of Minnesota." As Dr. Hewitt was secretary of the Minnesota State Board of Health, and as he had written extensively on the relation of the climate of Minnesota to disease, it may not be out of place to quote here the review as given in the *Journal*:

"The epidemic fevers, enteric, entero-malarial, intermittent and remittent, and cerebro-spinal meningitis, are shown to be present here, although not violent or extensively prevalent; and under the heading of 'Diseases of the Respiratory Tract,' the effect of this climate on catarrh, bronchitis, and phthisis is ably discussed.

"It seems to be pretty generally acknowledged that we do have a large amount of nasal catarrh in this state, which generally follows an attack of influenza; yet so many of the

*N. W. Lancet, Vol. 17, p. 31, Jan. 15, 1897.

†N. W. Med. and Surg. Jour., Vol. III, No. 6, p. 245, (Dec.) 1872.

invalids coming here from other parts of the country are found to have had chronic catarrh for years past, we incline to believe the disease is by no means peculiar to Minnesota. The benefits derived from a residence here by persons of a strumous diathesis are not overstated, and a timely warning is given that patients with well developed phthisis cannot expect relief."

Fifth Annual Meeting

The fifth annual meeting of the Minnesota State Medical Society was held in Saint Paul, February 4 and 5, 1873. Dr. W. W. Mayo presided.

An interesting item in the treasurer's report shows that the prize fund, though subject to call at any time, was invested at 12 per cent.

Dr. Staples of Winona was awarded the prize for his essay on Catarrhal Inflammation as an Element in Uterine Disease, and Dr. H. C. Hand of Saint Paul was prize winner with an essay on "Phthisis Pulmonalis." Competition was easy, however, since in each instance but one essay was forthcoming. The illustrations accompanying Dr. Staples' article are the first observed in the transactions up to this date.

Dr. Hewitt's proposed amendment to the By-Laws in reference to the formation of sections in the Society was laid on the table.

The report of the Committee on Practical Medicine for this session is made up of a study of Epidemic Cerebro-Spinal Meningitis. The report is written by Dr. Albert E. Senkler, Saint Cloud, who later moved to Toronto, Canada, and still later returned to Saint Paul, but the article is based on the experience of eight members of the profession who sent in data, in addition to Senkler's personal experience. As was true in other epidemics, Dr. Sweney's experience is widely quoted.

Ten new members were admitted to the Society, all nominated except Miss H. E. Preston. The objection to admitting women was paramount but the reason alleged for rejecting her application was because the Woman's Medical College, of which she was a graduate, had not yet been recognized by the American Medical Association.

The Committees on Obstetrics, Gynecology, Materia Medica and Ophthalmology presented no reports.

Dr. N. B. Hill of Minneapolis was elected president for the ensuing year.

The special committee appointed on revision of the Constitution and By-Laws submitted a report, which was laid on the table until the next meeting.

The committee made extensive revisions and urged that such a change be made in the By-Laws that all ethical questions be referred to a judicial council, and, as far as possible, be kept out of the public meetings, and after lengthy discussion these resolutions were adopted.

(To be continued in May issue.)

President's Letter

REDUCING DEATHS FROM CANCER

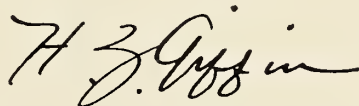

I

WE TURN aside from the war this month to a consideration of the ancient and honorable campaign against cancer. With over 150,000 deaths a year from cancer, nothing can be more important. It is well to consider what is being accomplished by lay organizations and by the medical profession. The American Society for the Control of Cancer and the Woman's Field Army are doing excellent work, especially in Minnesota, and deserve all the coöperation the Minnesota State Medical Association can give. Dr. M. W. Alberts, Chairman of our Committee on Cancer, has been very active and interested in this respect. It is suggested that the Woman's Auxiliary of our state association could very well coöperate more actively with this organization. Other lay organizations and also insurance companies have assisted in education of the public concerning symptoms. So thoroughly has information been disseminated that some physicians have feared the increase of cancerphobia but I suspect that those who develop cancerphobia would have some type of "phobia" in any circumstances. Abnormal fear is a psychotic phenomenon.

What is the State Medical Association doing and what is the physician's responsibility? The Medical Association through its committee on Public Health Education, its radio talks and press releases is assisting very effectually in education of the public. The University at its Continuation Center and the State Association by its packet of the month are giving postgraduate instruction in early diagnosis and treatment. But in the last analysis an improvement in the situation is the responsibility of each attending physician and each patient. The physician must "keep up" with the education of the public and the patient must accept the physician's advice. When a patient presents himself for examination he deserves a conscientious study of the case and not a pat on the back. Reiteration of the instances of cancer of the rectum which have been operated upon for hemorrhoids has led to a very marked improvement in early diagnosis of cancer of the rectum. The general use of x-ray and lately of gastroscopy has improved statistics on the diagnosis of cancer of the stomach. The situation with respect to cancer of the breast is not so favorable. There is a general tendency to observe tumors of the breast—and the patient may not return at the appointed time for observation. Definite nodules and discrete areas of mastitis are easily removed for microscopic examination and should not be "observed." Diffuse involvement of the breast during lactation should not be confused with "caked" breast. The physician should not hesitate to have early consultation in a situation so important. Consultation is as necessary for tumors of the breast as for tumors elsewhere. Their very accessibility is apt to lead to fatal procrastination. Approved cancer clinics are essential and fortunately are available in this state. If each of us will assume his responsibility with respect to cancer of the breast, real progress will have been made in early diagnosis and cure. Prevention of cancer must await further research.

II

I would like to call attention to the free home for people suffering from incurable cancer recently opened in Saint Paul—Our Lady of Good Counsel Free Cancer Home. Details are given on page 218 of the March, 1942, issue of MINNESOTA MEDICINE.

THE DOCTORS AND THE AMERICAN RED CROSS

THE communication in this issue from Dr. John
S. Lundy, chairman of the First Aid Red
Cross Committee for the State Association,
should be read and the purposes carried out by
all in a position to serve in our civil defense pro-
gram. The item of standardization is given first
emphasis: everything in the First Aid Red Cross
manual may not exactly express what each one
teaching a group would like to express. How-
ever, there is not time to depart from a general
method which has already proven its worth.

The physicians in each community must not lose

the opportunity to hold to their time honored po-
sition in the field of direction of matters primarily
medical. We shall need all possible salvage (and
there is always considerable) from this war period
and effort. There is a large group of women
ready and eager, searching for outlets for their
skills in the routine of Red Cross. Then if fate
visits upon us actual local bombing and devasta-
tion the field work will call for more than pa-
triotic display: actual detailed training and expe-
rience will be indispensable. As for the lady
who came into a Red Cross group and said, "As-
sign me some important assignment; no puttering
and fussy detail," even she has a place, if some-
one can help her find it.

E.L.T.

CIVILIAN DEFENSE IN MINNESOTA

A COUNTRY at war today requires, in addi-
tion to its armed forces, provision for
civilian defense. Although the interior of the
country is not so likely to suffer from bombing
and sabotage of industrial plants, means of trans-
portation and communication are an ever-present
hazard. For this reason organization for increas-
ing the protection of the state by the addition of
volunteer fire fighters and police, and the provi-
sion for greatly augmented emergency medical
aid in the event of unusual disasters is vital.
The medical profession has of necessity an im-
portant part to play in this part of the program.

In providing for the medical part of civilian
defense in the state, the Governor appointed Dr.
A. J. Chesley, secretary of the State Board of
Health, to organize this phase of defense. Dr.
Chesley has called in the state associations of
physicians, dentists, pharmacists, veterinarians,
nurses and hospitals for their coöperation, and
he has appointed health officers throughout the
state to coördinate the local organizations of the
above mentioned professions. Committees have
been, or are being, appointed by the local profes-
sional societies to provide for medical care in
case of need.

The needs for civilian defense differ in our
state from those in the sea border states. The

Governor has wisely adopted only regulations suited to our location.

The needs in our state are the greatest in the centers of population and industry. The medical phase of civilian defense will assist in providing for first aid units and their transportation to the site of the trouble, and ambulance transportation of victims in case the usual facilities do not suffice. Hospitals are to provide emergency first aid units consisting of two doctors, two nurses and two stretcher bearers, and a car for their transportation, all on call day or night. Such a unit should carry equipment in the form of splints, dressings, et cetera, and the unit should be ready to respond at a minute's notice. The doctors in such a unit need not be trained surgeons, for victims in need of operations will be transported to hospitals for operative care. Provision should be made for sufficient ambulance transportation. The offer of the State Association of Morticians to provide emergency transportation should aid in solving this problem. Doubtless local Red Cross units have station wagons in their motor aid group, which can be easily converted to carry one or two victims on stretchers. In addition to these preparations, plans have been made in the larger cities for first aid centers in outlying districts where supplies will be available day or night for neighborhood doctors and nurses. Certain industrial plants, particularly those on twenty-four hour shifts, and already equipped with a nurse and first aid equipment, constitute desirable first aid centers. We would suggest that physicians on call for such first aid service carry splints and a first aid kit in the trunks of their cars.

The part played by the local hospitals is undoubtedly the back bone of the medical side of civilian defense. It is the part of each hospital to supply the first aid units and to provide for emergency surgical aid in case of need. Each hospital will utilize the service of its medical staff and its nurses and will have available a number of beds in case of emergency.

Associated in the medical part of civilian defense are other groups such as dentists, pharmacists, veterinarians and the State Sanitary Conference. Fully as important as the organization of defense units on paper, is the provision of a mechanism for calling out promptly the individuals and units when needed. In the larger centers there will be a central headquarters estab-

lished for receiving information and for sending out calls for various defense units.

PREPAYMENT MEDICAL PLANS

THERE appears elsewhere in this issue a summary of the first meeting held under the auspices of the American Medical Association devoted to the discussion of the various kinds of prepayment medical plans in operation throughout the country. Meeting the cost of illness often is a difficult matter. The medical profession is interested in working out the best methods of financing the various items involved.

Many commodities are today purchased on the monthly installment plan—doctor's services included. No particular mechanism is needed to provide for monthly payments on doctors' bills, although it must be admitted that patients are more likely to pay a loan company regularly than a doctor.

It is, however, the hazard of the costly illness usually requiring hospital and nursing care as well as the services of a physician or surgeon which has prompted so much present-day discussion. Even those on a small income have no real difficulty in paying for an occasional visit from the general practitioner.

Insurance payable in small monthly installments affords an answer to the problem for many and is the basis of most of the organizations in operation. There has been, of necessity, much groping in the dark because of lack of experience and statistics.

Hospital insurance went through the same groping process and is apparently becoming firmly established. It is to be hoped the same will be true of medical insurance, although its problems are more involved. The fact that few like to be patients in a hospital and the provisions made by hospital associations to increase the benefits to members according to experience make it unlikely that much abuse will be made of membership. When it comes to a physician's services experience is less predictable.

Some prepayment medical organizations are confronted with fine legal distinctions. If they pay their own doctors and limit members to the services of designated physicians, they are practicing medicine and it is illegal for a corporation to practice medicine. If they agree to pay doctors' bills and allow free choice of physician their services are in the nature of insurance. Free

choice of physician is apparently the distinguishing feature between legality and illegality. Free choice of physician is what the medical profession has insisted is a requisite for best medical service. Free choice of physician is what some think is not at all necessary for the other fellow, but insist upon for themselves. Fortunately, most Americans value highly this feature of the American way of life.

AMERICAN COLLEGE OF PHYSICIANS MEETS IN SAINT PAUL

WAR or no war, it was the consensus of opinion of the officers and the Board of Regents of the American College of Physicians that the annual meeting of the College should and would be held in Saint Paul in April. Plans had gathered considerable momentum before Pearl Harbor and the momentum of such a large organization is considerable.

The program has long since been in the hands of its members. Dr. Roger I. Lee of Boston is this year's president and George Morris Piersol of Philadelphia, the secretary-general. The Board of Regents represent the continent from Boston to San Francisco and Montreal to Galveston.

The College meets in Saint Paul from April 20 to 25 on invitation of the Ramsey County Medical Society, backed by the Hennepin, Saint Louis and the Olmsted-Houston-Fillmore-Dodge County Medical Societies, the Minnesota Society of Internal Medicine, the Minnesota State Medical Association, the Medical School of the University of Minnesota, and many individuals in positions official or otherwise. The program speaks for the efficient management of Dr. John A. Lepak, local chairman, supported by the local committees.

Each morning during the session (except Monday) will be devoted to clinics at the Saint Paul hospitals and the University by visitors and local physicians. Panel discussions will occupy each noon hour (except Monday), and will be presided over by Minnesota physicians assisted by visitors. General sessions consisting of addresses by visiting physicians for the most part will occupy each afternoon.

Following the evening scientific program on Monday the annual smoker will be held by the College. The Ramsey County Medical Society will stage a light entertainment on Tuesday eve-

ning. The annual convocation, at which the president will give his address and newly elected Fellows will be presented, is to be held Wednesday evening and will be followed by a reception and dance at the Hotel Lowry. The banquet is scheduled for Thursday evening. Dr. Lepak will act as toastmaster and guests will be addressed by Dr. W. A. O'Brien.

Attendance at the sessions is not limited by any means to members of the College. Members of Ramsey and Hennepin County Medical Societies, interns of the various Saint Paul hospitals, medical students at the University of Minnesota and the Mayo Foundation, and members of the Medical Corps of the United States and Canada will be admitted free. Other qualified physicians may attend upon payment of a \$12.00 fee (which includes a year's subscription to the *Annals of Internal Medicine*).

Teas, luncheons and other forms of entertainment, in addition to the evening social affairs, will be provided the visiting women.

Mention should be made of the technical exhibits. Effort has been made to limit the exhibits to those of scientific interest in internal medicine, all irrelevant products having been excluded.

While the annual sessions of the College of Physicians might well be of interest to the profession in general, they are held primarily for those interested in internal medicine. The meeting of the College in Saint Paul this month provides a rare opportunity for internists of the North-Central district of our country.

CONFERENCE ON MEDICAL SERVICE PLANS

The first Conference on Medical Service Plans was held in Chicago on February 14, 1942, at the headquarters of the American Medical Association and the Palmer House. A total of sixty-four persons were present, including representatives from operating and proposed medical service plans in seventeen states and officers of state and county medical societies.

Dr. Olin West, Secretary and General Manager of the American Medical Association, welcomed the representatives and stated: "You are distinctly a part of a great movement that is essential to the welfare of the people of this country and it is highly desirable that you should get together to exchange information and opinions in order to arrive at a basic understanding of the problems involved."

Mr. J. D. Laux of Michigan Medical Service, who was elected Chairman of the Conference, indicated that interest in some form of prepayment for medical services has been moving along three well-defined fronts: (1) group clinic or consumer plans such as the Ross-

Loos Clinic or the Transport Workers Medical Plan, of which there are seventeen such plans in operation with a total enrollment of 100,000 persons; (2) employee-employer mutual benefit associations (300 in operation) and the commercial insurance company plans (at least 250) providing cash indemnity benefits totaling \$365,000,000 annually; and (3) non-profit medical service plans sponsored by medical societies, of which there are 33 plans in operation in 9 states with an enrollment in excess of 750,000 persons. The non-profit medical society sponsored programs are developing most rapidly and give the best promise of contributing toward a better distribution of medical service.

The entire day was devoted to consideration of the basic principles and major problems involved in medical service and limited surgical benefit programs sponsored by medical societies. The following are some particularly pertinent points brought out in the discussion:

- Contract practice plans limiting service to a small number of physicians cannot provide a satisfactory service for an entire community. Non-profit community-wide or state-wide service plans are the proper type of organization for prepayment of medical services.

The statement that voluntary plans lead to compulsory insurance applies to the chaotic situation created by a multiplicity of lay controlled or commercial plans, not to medically sponsored community programs.

- In medical society sponsored programs, the contribution of the profession is the offering of services without additional charge to persons in the under-income group. Under a plan providing cash indemnity, the only thing the medical profession furnishes—service protection to the individual—would be taken away.
- Experiments in the full coverage type of medical service plan are being undertaken to determine the effect of such plans on the private practice of medicine; how such plans affect the physician-patient relationship; what problems arise in connection with the practice of specialists; the difference between urban, rural, and metropolitan practice; and all general problems relating to medical care.

- A differential arrangement for specialists is a problem which one medical service plan treats in the following manner: When a subscriber uses a specialist as his family physician, the specialist receives general practitioner fees for such service. However, in the event the subscriber is referred to a specialist by his family physician for special services, an increased fee is paid. To be eligible for increased fees, the specialist must confine himself strictly to his specialty.

- Enrollment based on individual physical examinations does not furnish as good selection as group enrollment.

- The desirability of establishing somewhat uniform or model legislation for medical service plans was emphasized.

- The question of the extent of joint operations with hospital service plans and the appropriate basis for cooperation led to the establishment of a committee to meet with a committee from the hospital service plans.

- It is of utmost importance to establish a centralized agency for the collection and dissemination of information. R. G. Leland, M.D., Director of the Bureau of Medical Economics of the American Medical Association, outlined a program of co-ordination through establishment of a glossary of terminology, an organizational outline of the plans, and a composite tabulation of financial and statistical reports.

The Conference concluded with the appointment of a committee to determine the best method of establishment of a permanent organization of medical service plans throughout the country.

Communication

Committee on First Aid and Red Cross

The members of the First Aid and Red Cross Committee were unanimous in the belief that, because of the urgency of the present situation, they would follow the standard Red Cross First Aid Textbook in teaching first aid.

It was agreed also that, in order to avoid confusing the students, the book would be followed just as it is, without expression of the instructor's personal disagreement with the text.

The instructor, it is believed, should avoid offense to any social or professional group.

It was suggested that the physician be the executive officer, that he lay the plans and direct the course, that he personally give the primary instruction but that he utilize available persons in conducting the necessary drills.

The medical profession is asked to make first aid training available to the hundreds who will be required to take it and to the thousands who will desire it. Air raid wardens, school bus drivers and victory aides are examples of persons who already are required to take it.

The physician is best qualified of all persons in the community to direct the energies of the host of people who are insistent on giving their help. He need not fear that the entire burden will fall on his own shoulders.

As a corollary of this, the physician may be sure that many organizations, the membership of some of which is composed of women, are eager to support his efforts. As an introduction to utilization of these groups, the physician should urge participation of the Women's Auxiliary to the Minnesota State Medical Association.

Obviously, in the development of the entire program, the prompt support of officers of county and regional medical societies is essential.

(Signed) JOHN S. LUNDY, M.D.

Chairman of the Committee on First Aid and Red Cross of the Minnesota State Medical Association

MEDICAL ECONOMICS

of the

Minnesota State Medical Association

George Earl, M.D., Chairman

CORRECTIVE SERVICE TO SELECTEES

Preliminary arrangements for rehabilitation of selectees were already under way in Minnesota as this issue went to press.

Selective Service regulations call for these corrective services to be given by home physicians and dentists of the selectee's own choice. But these physicians and dentists, with the exception of already qualified draft board examiners, must be accepted by the state director of the system before they may participate.

Medical examiners for local draft boards were sent their applications direct by the director of the system because officials in charge regard them as entitled to special consideration in view of their extensive unpaid service with the draft.

To facilitate application on the part of all other qualified practitioners, letters were sent to all members in March, urging them to secure their own application blanks from local draft boards. These blanks were to be filled out and returned as promptly as possible to the draft board to be forwarded to the director of the system in Saint Paul.

The regulations make it clear that this corrective service is not to be thrown wide open for any disability which the selectee may wish to have treated.

Fees will be paid by the Selective Service System for services previously authorized by the Selective Service authorities, only, and only to practitioners who have applied in the regular manner.

The procedure for authorizing treatment had not yet been announced as this issue went to press.

ALREADY AT WORK

Minnesota's committees on Procurement and Assignment of Physicians are already at work reporting on the qualifications and availability of Minnesota physicians for service with the armed forces.

So far, only names of men who expressed themselves on the first Procurement and Assignment questionnaire as willing to serve, have been checked. The main body of the work will come after the new questionnaire from the P and A, due early this month, comes out.

In preparation, lists of all physicians in every district in the state are being sent to committee members. These lists are on prepared blanks, filled out as to age and specialty of the physician. The county committee will then fill out the blank as to the availability for service of the physician, if not for military service, for other necessary public services such as the health service, industry or civilian practice in other communities stripped of physicians. The committee will make its decisions solely on the basis of community need. It is no part of their responsibility to pass upon claims for dependency.

Community Need Is Crux

If a community is already served by a sufficient number of physicians not qualified for combat service, even if it means a greater demand on their services, then the committee will mark the younger man in question as available for military duty. If a community can spare the services of an older man or a man obviously incapacitated for military service, the committee will mark him available for nonmilitary duty, that is, for medical practice in a community stripped of medical services, or in industry or in the public health service.

These lists of names went out to county committees before the first of April and are now being completed, according to local information, by the committees. They will be forwarded to the state committee and will be at hand for immediate reference as names are sent to Minnesota for checking from the Procurement and Assignment Service in Washington.

Begins With Physician

It is the hope and plan of all the combat agencies and the Procurement and Assignment Service that future military needs may be met under this system. The plan depends upon the willingness of physicians to serve wherever they can best serve, at home or in the armed forces, as expressed on the questionnaire which will reach them all within a short period. With the information on the questionnaire at hand and the supplementary advice of state and county committees, all physicians will be selected for the services which need them without stripping civilian communities or civilian needs. All physicians called in the draft will be referred to the Procurement and Assignment Service and will be permitted to apply for commission, if they are found to be available.

As emphasized repeatedly before, the Procurement and Assignment Service has no jurisdiction over members of the Reserve Corps.

Lapel Button

All who fill out and return their Procurement and Assignment questionnaires, however, will receive a signed certificate and a lapel button which will indicate that they have offered themselves for whatever service they can best give to the war. If they remain at home, under those circumstances, it is because impartial judges have decreed that they are needed at home—not because they have dodged their duty to their country.

TAX MEASURE OR SOCIAL PLANNING?

Which came first, "the chicken or the egg"?

American Hospital Association executives and "Blue Cross" directors posed the old question at a meeting in New York, recently, with reference to proposed increases in Social Security taxes. What prompted the new proposals? Was it the long-considered plan for extending social security to hospital service, or was it actually the need for new revenue to be derived by two billion dollars in payroll taxes which such an extension would provide?

If the proposal is actually another measure for revenue, then it should certainly be debated solely on grounds of its expediency as a tax-raising measure and rejected on those grounds. It is

obviously indefensible to raise war funds by measures which, once written into the law, cannot be repealed when the war is over without dislocating and endangering our whole Social Security system.

If the proposal is an honest piece of social legislation proposed as part of an expanding program of social planners in Washington, then it needs more study and debate than can be given it in a war crisis. It should wait until the crisis subsides and Congress can be reasonably certain of what lies ahead for Americans.

Would End "Blue Cross"

It is more than likely that the plan to provide \$3.00 daily for hospitalization out of Social Security funds—in exchange for doubling the current payroll tax—would eventually alter America's unique and efficient voluntary hospital system. It is certain that it would end the most extensive and promising privately promoted social experiment of these times, the "Blue Cross" hospital service system. This system now serves thousands of Americans well and it is being extended rapidly.

Difference Is Fundamental

Said Dr. S. S. Goldwater, head of the Associated Hospital Service in New York, at this meeting:

"I don't want to oppose something constructive that the Government wants to do; but I do want the Government to keep its hands off something constructive that we are doing. The motives of the President as expressed in his recommendations in January regarding increased benefits for contributors to the Social Security program are undoubtedly honorable and should not be opposed on that ground but rather on the ground that, in so far as we can see, they are being converted into bad methods. What the President says he wants to do is what we want to do. There is, however, a fundamental difference in method. . . .

"Local organization and control will produce the best results in hospitalization and any Federal approach to interference with the fiscal affairs of hospitals leading eventually to control by a central Government bureau would be a tragic affair for the people of this country. There is justification for the interest of a humane government in the question of whether hospital service has been made available on suitable terms to a great mass of the people; but this inquiry should also take into account the fact that voluntary, locally directed hospital service plans have made Government intervention unnecessary.

Local Failure Not Tragic

"Exaggerated statements have been made in Washington and elsewhere as to the lack of hospital care. There may be some communities where adequate hospital facilities are lacking or where good hospital service is difficult to obtain. But these are very few in this country. . . .

"Assumptions that we must do as other countries have done regardless of our achievements are certainly not justified, especially in a country where freedom is valued and where the principle of local self-government is supposed to be sacred. . . .

"Moreover failure in a locality, if it occurs, is not the tragic thing that country-wide failure would be. Hospitals must be left free to take such action as their communities require without having to wait for approval from Washington based upon imperfect knowledge of local conditions.

"My own experience in New York showed me how far short Government hospitals can fall from the perfection which has been attributed to them. Perfect conditions do not exist anywhere and even in New York, where I worked as head of the city's hospitals—and I worked under conditions as favorable as can be expected of government—the story has not yet been told of impediments placed by government circumlocution in the way of anybody attempting to administer a large group of hospitals from a central office. The system as a whole failed to accomplish what I had in mind for the city because of the onerous conditions under which government work of all sorts had to be done. It could hardly be otherwise if the Federal government attempted to exercise any measure of control over voluntary hospitals, as it inevitably would do sooner or later under plans proposed by the Social Security board.

Can Fit All Needs

"The fact is that we have in the voluntary non-profit hospital field a positive plan for the pre-payment of hospital bills by the public which has, in a few short years, demonstrated its capacity to serve and the eagerness of the public to take advantage of it. If the government will keep its hands off we will be able to develop plans hereafter that will fit the needs of all groups in the population, down to those of the lowest incomes, with local supervision and control and with local responsibility. We are asking the Government to stand by and give us its blessing to encourage us in the work we are seeking to do rather than to hamper us by ill advised interference, however well meaning, which offers a serious threat to the voluntary hospitals system and to free medicine. . . ."

The March issue of *Hospital Management* reports a total of seventy-one approved "Blue Cross" hospital service plans in the United States, representing twenty-nine states and two provinces.

THE COUNCIL MEETS

Defense

Health aspects of Civilian Defense have not yet been worked out in detail, Dr. A. J. Chesley, secretary of the State Board of Health, reported to the Council at the February meeting. It was decided, however, that members of the Council would act as advisers in these matters in their districts. They will meet with chairmen of city and county Defense Councils and with local health officers to develop and coördinate local plans.

Dues

The question of refunding dues of members in active military duty was thoroughly discussed at the request of one large society at this meeting. All Council members felt that the work of medical organizations at home is too important to permit such refunds.

It was pointed out that a large number of societies are now assessing their own members to cover local and state dues of colleagues who go into service. Furthermore, the House of Delegates ruled in 1940 that only officers under the grade of captain who are in need of assistance should be excused from paying dues—and then only with approval of the Council.

Fifty Years

A new honorary organization, the "Fifty Club," was established by the Council at this meeting. It will be made up of members who have practiced medicine for fifty years or more. All will receive a lapel button engraved with the name of the association and the numeral fifty at the first presentation ceremony to be held in connection with the 89th annual meeting in Duluth. The presentation will be a regular feature of the meeting each year, thereafter, and special invitations will be issued to all who are able to attend. Those who are not able to attend will receive their awards at home.

Preliminary counts showed a considerable number of physicians, some of them still in active practice, who are eligible for "Fifty" awards in Minnesota.

Insurance Studies

Two sub-committees of the Committee on Sickness Insurance will study sickness insurance

plans all over the country this year with a view to the possibility of drawing up a workable plan for Minnesota, it was decided at this meeting. One of these committees will investigate enabling acts passed in other states, an essential first step to any non-profit insurance plan. The other will review actual provisions of existing medical service plans with a view to sifting them for Minnesota requirements. A report on both studies will be submitted to the House of Delegates in June.

County Added

Beltrami county was selected, with the approval of the Council, for a third experiment in medical service for Farm Security clients in Minnesota. The first two, in Morrison and Ottertail counties, are now five months old and preliminary reports from the FSA and the physicians involved are not unfavorable. Both admit, however, that insufficient time has elapsed as yet to judge of the ultimate success in either locality. Dr. Richard F. Boyd of Milwaukee, regional medical director of the FSA, presented the matter to the Council and expressed the appreciation of the government for the coöperation of physicians in both counties.

Nurses' Training

A joint committee of nine, representing the medical and hospital associations and the State Board of Nurses Examiners, will study problems of nurses training as they effect especially the rural hospital. The plan, drawn up by the Committee on Interprofessional Relations, was approved by the Council at this meeting. The new committee will act as a liaison body before which all the interests concerned, including the public, the hospital, physicians and nurses, will be aired and thoroughly discussed. Training regulations which will protect nursing standards and still not deprive smaller hospitals of well-trained nurses will be the objective of the committee. Drs. F. J. Savage, Saint Paul, C. M. Johnson, Dawson, and P. F. Meyer, Faribault, were appointed medical representatives to this committee.

Julian F. Du Bois, M.D., Secretary

St. Paul Abortinist Loses Appeal in Supreme Court

Re: State of Minnesota vs. Georgiann Tennyson, also known as Ann Tennyson.

On March 6, 1942, Mrs. Georgiann Tennyson, fifty-three years of age, lost her appeal from a conviction for criminal abortion, in the Supreme Court of Minnesota. The decision of the Supreme Court was unanimous. Mrs. Tennyson, who resided at 1719 Ross St., Saint Paul, was convicted by a jury in the District Court of Ramsey County, on May 23, 1941, and was sentenced by the Honorable Hugo O. Hanft, Judge of the District Court, to a term of not less than two and not more than eight years at hard labor in the Woman's Reformatory at Shakopee. Mrs. Tennyson's sentence was doubled due to the fact that in 1928, she had a previous conviction for criminal abortion. At that time, she was known as Ann Herbert. Mrs. Tennyson was taken to Shakopee on March 6, 1942, to commence serving her sentence.

In the present case the Supreme Court of Minnesota made a very careful review of the laws of this State concerning the crime of abortion and previous decisions of the Supreme Court. The opinion written by the Honorable Harry H. Peterson, Associate Justice of the Supreme Court, held that there was no merit in Mrs. Tennyson's contention that the girl upon whom the abortion was performed was an accomplice and, therefore, Mrs. Tennyson could not be convicted unless the girl's testimony was corroborated. The Supreme Court of Minnesota definitely stated that

"A woman upon whom an abortion is performed or attempted is not an accomplice in the commission of the offense."

The Supreme Court also held that it was not prejudicial for the trial court to have permitted a physician to testify on behalf of the State

"that the administration of the jelly substance in question to produce an abortion was dangerous to the life of the woman. We cannot perceive that any possible prejudice could have resulted. It is impossible to believe that any juror of ordinary intelligence would not know, without being told so by a doctor, that an attempt to produce an abortion by the administration of any medicine or substance or the insertion of an instrument into the uterus would be dangerous."

Mrs. Tennyson is an old offender in the abortion racket and deserves little consideration. There is no excuse whatever for Mrs. Tennyson's having been engaged in such illegal activities. Her husband has been employed for some time by the City of Saint Paul as a fireman. The Supreme Court's decision culminates a long fight waged by the Saint Paul Police Department, the State Board of Medical Examiners and the Ramsey County Attorney's office to put Mrs. Tennyson out of circulation. The case was diligently prosecuted by Mr. James F. Lynch, County Attorney of Ramsey County, and is another example of the splendid coöperation given by Mr. Lynch's office in the prosecution of those who violate the medical laws of the State of Minnesota.

Duluth Woman Sentenced to Four-Year Term for Abortion

Re: State of Minnesota vs. Millie Meyer.

On February 11, 1942, Millie Meyer, forty-nine years of age, was sentenced to a term of not to exceed four years at hard labor in the Women's Reformatory at Shakopee, Minnesota. The sentence was imposed by

the Honorable C. R. Magney, Judge of the District Court, following the defendant's conviction by a jury of the crime of abortion.

Mrs. Meyer, who resided at 108 No. 58th Ave. West, Duluth, was arrested on January 15, 1942, by members of the Duluth Police Department, when it was learned that a twenty-five-year-old Duluth girl had an appointment with Mrs. Meyer for the purpose of having an abortion performed. On January 16, R. E. Donaldson, Chief of Detectives of the Duluth Police Department, filed a complaint against Mrs. Meyer charging her with the crime of abortion. Mrs. Meyer demanded a preliminary hearing which was had on January 22, 1942,

in the Municipal Court of Duluth. Following the hearing, she was held to the District Court for trial. The trial commenced on February 3, and ended on February 5, with the jury deliberating only two hours and returning a verdict of guilty.

This conviction marks the third successful prosecution, during the past year against abortionists in Duluth. It demonstrates the splendid work being done by the Duluth Police Department under Chief Elmer Stovern and Chief of Detectives R. E. Donaldson, and the County Attorney's office of St. Louis County. The case was tried for the State by Mr. Walter F. Dacey, assistant to Mr. Thomas J. Naylor, County Attorney.

CONSERVATION OF MAN POWER

Every industry in this state, whether concerned entirely with defense work, or completely of a private nature, has, since "Jap Sunday," increased its tempo to a tremendous pitch. This increase has imposed a great strain on all the components of production, including the machines of flesh, as well as the machines of steel.

Mechanical engineers, plant managers, and machinists can glibly quote the stress, strain, hours of production, etc., each machine of steel is capable of withstanding in producing its maximum efficient output. How meager, in comparison, are the facts in regard to the machines of flesh which are the most important cogs in our "all-out" war of production.

Out of World War I medical men in all fields from Psychiatry to Roentgenology, and Surgery to Dermatology, gleaned valuable statistics and information which aided the progress of Medicine immeasurably. In World War II, when for every man on the battlefield, it has been variously estimated twelve to sixteen men are necessary in industry, the opportunities for Industrial Physicians, and Surgeons, to correlate all facts of fatigue, efficiency, and nutrition, as well as the effects of rest periods, general health measures, and planned feedings on the human machine, should be collected and utilized to the fullest extent.

Medical Profession Responsible

The conservation of man power resolves itself around the education of Industrial Physicians and Surgeons, as well as all Physicians in any way connected with the health and welfare of workers, education of plant owners and operators, and health education of the great masses of workers. The responsibility for this tremendous task rests squarely on the shoulders of the medical profession as a whole, but more surely so on the increasing corps of Industrial Physicians and Surgeons.

To quote from a recent editorial in the *Journal of American Medical Association*, "Neither employes nor physicians yet fully comprehend how vast a contribution could be made to the war effort by a well-organized health program. A reduction of only ten per cent in the four hundred million man days now lost annually due to illness and injury would produce, if applied to these va-

rious tasks, five capital ships, sixteen thousand tanks or nine thousand bombers.

Worker Most Valuable Machine

With the challenge clear what can we as Physicians do to conserve this vital factor in Victory, Man Power? First, I believe an organized, as well as individual, effort should be made to bring to the attention of the Manufacturers, the necessity of recognizing the fact that their most valuable production unit is the individual worker and not the steel machines. Acquaint them with the facts available in regard to the maintenance of the general health and efficiency of their employes. Warn them against the exploitation of health and efficiency by too much "over time" and constant days of work, with no periods of rest or relaxation. The experience of British Industry, that more than fifty-six to sixty hours per week of work for men, and forty-eight hours of work per week for women leads to increased illness, absenteeism and increasing accidents should be quoted in support of these contentions. Secondly, the workers themselves should be acquainted with measures of health promotion and sickness prevention by various educational means. No one method will reach all workers so poster campaigns, personal interviews, group health conferences and classes, motion pictures, payroll inserts, etc., should all be utilized. Repetition in all forms is necessary to keep impressing the worker of his duty in maintaining his health and efficiency, to contribute his best at all times, but particularly now, in this war for Victory. Stress keeping fit, rather than medical treatments and diseases and always employ the simplest of lay terminology. The Bureau of Health Education of the American Medical Association has many pamphlets available that can be readily obtained to assist in this form of education.

Lastly the medical profession as a whole must keep abreast with the many phases of Industrial Health as applied to the maintenance of the health and efficiency of all workers whether treated individually, as private patients, or in groups. Answers to any specific questions can always be obtained through your Minnesota State Medical Industrial Health Committee which is only too eager to assist physicians in maintaining their part of this tremendous responsibility.

EUGENE E. SCOTT, M.D.

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, February 11, 1942. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the president, Dr. Martin Nordland.

There were forty-nine members and one guest present. Minutes of the January meeting were read and approved.

The Secretary read a letter from Dr. J. F. Corbett expressing his appreciation of the Academy's action in having Dr. Corbett's name transferred to the Honorary Membership list.

The scientific program followed.

Dr. Walter E. Camp gave the following paper with two case reports, illustrated by numerous lantern slides.

MALIGNANT EXOPHTHALMOS FOLLOWING THYROIDECTOMY IN GRAVES' DISEASE

BY WALTER E. CAMP, M.D.
Minneapolis, Minnesota

Exophthalmos, or proptosis of the eyeball, is only one of a number of disturbances which affect the eye and orbital contents in Graves' disease, or thyrotoxicosis. Plummer and Wilder in 1934, reporting on 2000 cases of exophthalmic goiter, found exophthalmos present in 55 per cent. Other investigators have reported exophthalmos to be present in from 35 to 75 per cent. Plummer and Wilder also showed that previous to thyroidectomy there was a positive correlation between the exophthalmos and the basal metabolic rate, and also that the incidence of exophthalmos in exophthalmic goiter has decreased in later years.

Before discussing the pathogenesis of exophthalmos associated with hyperthyroidism, and discussing rather briefly the relationship between the two, I want to report two cases of malignant exophthalmos which developed following thyroidectomy and in which all other signs of thyrotoxicosis have disappeared.

Case 1.—The first patient, whom I saw with Dr. Regnier, was a farmer thirty-one years old, who entered the hospital January 19, 1940. His symptoms were those typical of hyperthyroidism: namely, tachycardia, tremor, nervousness, loss in weight, dyspnea on exertion, and moderate exophthalmos with occasional diplopia. These symptoms had all developed about one year before admission. Examination showed a typical "thyroid stare," moderate exophthalmos with positive Stellwag and Graefe signs. Pulse rate was 90. The thyroid was moderately enlarged and there was a gross tremor of the hands. Basal metabolic rate was plus 43 per cent. Thyroidectomy was done January 22, 1940, which consisted of a subtotal lobectomy with complete removal of the isthmus and pyramidal lobe. Postoperative recovery was rapid and uneventful.

He had no further complaints until July, 1940, six months following the operation, when the exophthalmos became progressively worse. The conjunctiva of both eyes became chemotic and he was unable to close the

lids completely. The left eye was slightly more proptosed than the right and developed three small ulcers on the lower half of the cornea in the exposed area that could not be completely covered by the eyelids. Exophthalmometer readings made at this time were 26 for the right eye and 28 for the left. His basal metabolic rate was minus 10 per cent and all other signs of hyperthyroidism had disappeared. He was hospitalized, given atropine ointment, and a moist chamber dressing to further protect the left eye. X-ray therapy to the pituitary was begun and continued until he had had 950 Roentgens on each side. In ten days the ulcers had healed completely and on September 24, 1940, the exophthalmometer readings were 23 for the right eye and 24 for the left eye. To date, about a year and a half later, he has had no further trouble.

Case 2.—The second case presented a more difficult problem to handle, and had, as you will see, a much more malignant course. I am indebted to Dr. Nordland for the privilege of seeing this case and for his rather complete history and summary of her findings. She was a single woman, thirty-four years of age. Her history of hyperthyroidism dated back about three years and consisted of nervousness, fatigue, tachycardia, loss in weight, and exophthalmos. The thyroid was uniformly enlarged and firm on palpation. The exophthalmos was mild in degree, but was not measured by exophthalmometer at this time. The basal metabolic rate was plus 33 per cent; pulse rate 108. After rest in bed and Lugol's solution, the basal rate was plus 23 per cent. On July 2, 1940, a subtotal lobectomy of the thyroid was done. Recovery was rapid, with disappearance of all symptoms except the exophthalmos. The basal rate three months following the operation was minus 10 per cent; and six months after operation was minus 1 per cent. At this time, namely six months following the operation, the exophthalmos had rather markedly increased. She was seen at this time by Dr. Frank Burch, who found diplopia and marked weakness of convergence. The exophthalmometer readings taken by him were 26 for the right eye and 22 for the left eye. The patient now was absent from observation for about three months. At this time she was seen by Dr. Edward Burch, who found the proptosis of the right eye had increased from 26 to 29, and an ulcerative keratitis was developing in the right eye. She was given a protective glass and advised by Dr. Burch to have an orbital decompression to preserve vision. The left eye had remained at a reading of 22, which was the same as three months previously.

The exophthalmos of the right eye gradually increased during the next month, but the excoriated cornea showed little change. She was hospitalized, and given large doses of Lugol's solution and thyroid extract. X-ray therapy to the pituitary area on each side was given in doses up to 480 Roentgens. The right eye was protected by a moist chamber. The proptosis remained about the same, and the patient at this time was seen by Drs. Benedict and Adson, who advised that an orbital decompression operation would probably not save the right eye. The corneal ulceration had rapidly progressed to necrosis and perforation. Enucleation of the right eye was done May 1, 1941. Immediately following the enucleation of the right eye, the exophthalmos of the left eye began to progress and on May 5, 1941, four days following enucleation, the exophthalmometer readings increased from 22 to 25. A moist chamber was used to protect the left eye and more x-ray therapy was given to the left orbit and both pituitary areas. A small ulcer developed on the lower half of the left cornea, but fortunately the ulcer healed and the proptosis gradually receded to a point where now the patient uses only protective glasses.

The conjunctiva and orbital tissues of the right orbit are still slightly prolapsed, nine months following enucleation.

This interesting case caused all of us who saw her considerable concern and worry, as at one time it looked as though she would lose her second and only eye.

The pathologic history of malignant exophthalmos is fairly well understood and has been partially demonstrated, at least in the microphotographs of eyes that have been removed. The pathogenesis of its development, however, has still not been satisfactorily explained. It has been shown that malignant hyperthyroidism can exist without exophthalmos and that malignant exophthalmos can exist without any symptoms of hyperthyroidism or thyrotoxicosis.

Both clinical and experimental evidence has proved conclusively that the thyroid enlargement, the thyroid epithelial hyperplasia, and the exophthalmos are due to hormones secreted or controlled by the anterior pituitary, or hypothalamos, or both.

It is interesting to follow through the literature for the past ten years and find "hints," deductions, or statements which gradually lead up to the present-day concepts of Hertz, Means, Williams, Collip, and of Heyl and Billingsley, that there are at least two and possibly three thyrotropic hormones, and that one or possibly two are responsible for the thyroid disturbance, and still another is responsible for the orbital trouble, namely, exophthalmos, diplopia, paresis of accommodation, Möbius, Dalrymple, Stellwag, and Von Graefe signs.

Hertz, Means, and Williams, of the Massachusetts General Hospital have elected to classify Graves' disease as an endocrine imbalance, and to subdivide it into (1) the classical type, in which exophthalmos is absent, or, if present, is well controlled by therapy or thyroidectomy; (2) the special ophthalmic type in which thyrotoxicosis is not manifest or has subsided following therapy or thyroidectomy, and the ophthalmopathy has become aggravated. They argue that there is a definite balance between the thyroid stimulating hormone (T.S.H.) or thyrotropin and the thyroid hormone or thyroxin. An excess of thyroid hormone supplied to the tissues produces hyperthyroidism. This excess of thyroxin in the tissues is due to an over-activity of the anterior pituitary or to an imbalance of the hypothalamos and the pituitary. The thyroid hormone promotes diuresis, while the T.S.H. promotes water storage, and would be effective in producing exophthalmos by local water storage within the orbit. Hertz, Means and Williams have shown that in the special ophthalmic type there is a higher output of T.S.H. in the urine than in the classical Graves' disease or in normal persons. They believe that thyroidectomy, after full iodination, is the best treatment for the classical type of Graves' disease, but that in the special ophthalmic type, thyroidectomy is not indicated and may even aggravate the ophthalmopathy.

Discussion

DR. H. B. ZIMMERMANN, Saint Paul: I have had a very interesting case recently which illustrates pretty much what Dr. Camp said about the association of two

types of symptoms. This young man developed unilateral exophthalmos associated with quite a high fever and systemic evidence of infection. It looked to be pretty obviously an inflammatory thing in the orbit. An incision was made behind the orbit and pus evacuated. The condition at that time was assumed to be an ethmoiditis. The wound drained profusely, the systemic symptoms of infection cleared up, there was some recession of the proptosis, but the vision in the eye was lost. A month or two later the patient developed definite symptoms of exophthalmic goiter. Up to this time it was a unilateral exophthalmos probably due to retrobulbar abscess. Now, as he began to lose weight, it seemed to be a case of Graves' disease. I was asked to do a thyroidectomy. I somehow had a hunch that something was going to be wrong and I advised the man I would do the operation but not to expect too much. I did the thyroidectomy. His toxic symptoms disappeared and I immediately had him put under Dr. Burch's observation. As predicted, the exophthalmos in the good eye continued until Dr. Burch became alarmed about this eye. Wallace Ritchie did a decompression from above and recently I think he has been much better, though I have not seen him since.

DR. E. A. REGNIER, Minneapolis: From Dr. Camp's report, I think both of these cases demonstrate several factors at work in exophthalmic goiter. Both patients had moderately high basal metabolic rates before being put under treatment. Subsequently, they had clinical cures with metabolic rates of minus 10 per cent. Operation did away with the toxic symptoms and still the exophthalmos continued.

A patient I saw a few years ago, a young woman, had been very ill, with a temperature of 105° to 106°, with what looked like acute follicular tonsillitis. After the fever subsided, she remained very ill and her pulse ran about 140, and basal metabolic rate was over 60. She was put on iodine treatment and developed bilateral exophthalmos. In about two weeks' time she was in condition to warrant thyroidectomy. After operation the exophthalmos receded in one eye and in the other eye it seemed to progress. She was given iodine in small doses for about eight weeks and then the exophthalmos receded in one eye entirely, which left her somewhat disfigured. One eye was prominent and much larger than normal. Whether or not the iodine had anything to do with inhibiting the exophthalmos is problematical and the unilateral exophthalmos became stabilized with no corneal complications. These three cases, demonstrate endocrine factors outside of the thyroid, probably in the anterior pituitary, which remain over-active for some time following removal of the toxic thyroid.

I would like to ask Dr. Burch what he has to offer us in the way of palliation in these cases short of orbital decompression?

DR. F. E. BURCH, Saint Paul: I have been unfortunate enough to see a number of cases similar to those so well presented by Dr. Camp, and including his case. Four eyes have been lost. The first one was seen in 1928 and has been fully reported in the November, 1929, MINNESOTA MEDICINE. Progressive exophthalmos began in one eye eighteen months after a subtotal thyroidectomy and was at first diagnosed as a pseudotumor of the orbit. A Kronlein exploration was done elsewhere. The biopsy revealed nothing but edematous fat. Eventually both eyes were lost.

There are several difficult things about these post-operative malignant exophthalmos cases. They come to the ophthalmologists complaining of epiphora, frequently of diplopia, some followed by intense conjunctival chemosis, the diplopia frequently preceding the intense proptosis. The outstanding thing one finds on exploration or after exenteration is the enormous increase in size of the extraocular muscle, sometimes as

large as lead pencils. In the case mentioned, reported by me, there was an intense hypertrophic degenerative myositis of all the extraocular muscles, an increase in the orbital content of about 40 per cent, mostly due to edema. I do not know how to explain the enormous hypertrophy of all the muscles or just why diplopia developed so early and before marked proptosis. It is possible that this may be due to a pressure paralysis of the nerves supplying the extraocular muscles.

In Schmeltzer's work exophthalmos could be experimentally produced in animals in from ten to twenty days after injection of beef anterior pituitary lobe. He found that when the ganglion was removed on one side the animals developed binocular exophthalmos equally. That there is a thyrotrophic hormone factor with which the anterior pituitary lobe is directly concerned seems most plausible.

All but one of the seven malignant cases I have have had low, normal or subnormal basal metabolism. One case with progressive exophthalmos died without thyroid operation. None of these cases had any of the usually classical signs of hyperthyroidism at the time of the progressive exophthalmos. They did not have tachycardia nor were they particularly nervous. The Von Graefe, Stellwag and Moebius signs were absent in many cases later.

Treatment is difficult. They progress in spite of any attempt to suture the lids, do a canthotomy, incise the orbicularis or remove orbital fat. The cornea begins to break down, apparently on a purely trophic basis without any actual infection.

Three cases seen by me improved under thyroid therapy or Lugol's solution, in one case under administration of both thyroid extract and iodine.

I was fortunate enough to see one patient whose exophthalmos had been treated by decompression of the frontal and ethmoid. It seemed to me a less mutilating result than the one patient I have seen after a Naffziger decompression. At present I have a case under observation undergoing x-ray treatment of the pituitary, which probably also included the orbits. This has resulted in a reduction from 25 and 26 mm. down to 22 and 23 mm. in exophthalmometer measurements and the patient has had a very great relief from symptoms, especially headaches.

The non-operative treatment of these cases, in my opinion, is x-ray therapy of the pituitary (which probably also includes the orbits). The operative treatment for extreme cases should be a decompression of the frontal and ethmoids, or perhaps a Naffziger operation. The ophthalmologist is "on the spot" to know just how to handle each problem and certainly needs the help of the internist, radiologist, rhinologist and neurosurgeon.

DR. WILLIAM T. PEYTON, University of Minnesota (by invitation): If this is entirely a matter of hormones, it is remarkable that only one eye should become exophthalmic or at least that one eye should become more involved than the other. It is, however, not beyond the realm of possibility. Sometimes we see in girls at puberty one breast developing before the other.

I saw this second case described by Dr. Camp, at the time she had ulceration in the cornea of the second eye. I admit that I urged the patient to have orbital decompression; but in view of the end result, it would seem that she was right in refusing to have it done. The question is: should these patients have decompression or should they be given x-ray therapy? I have never done a decompression. It has been the policy at the University Hospitals to treat progressive exophthalmos with x-ray, and we have not found it necessary to perform operation later. However, the operation is neither difficult nor mutilating. It consists of an incision entirely within the hairline, raising up the

frontal lobe, removing the roof of the orbit and opening the capsule.

After Dr. Nordland invited me to come here this evening, I went down to the x-ray department and looked up the cases we have treated. Nine cases were treated. Two had lost one eye before treatment. Since treatment, one was followed three years without progression of the exophthalmos, five were followed one year without progression, one was followed a few months and found to have regression. Two were not followed.

Of course, we realize that a follow-up of only one year is not sufficient and that these people must be followed longer before definite statements can be given as to whether or not this treatment is effective. So far, however, no eyes have been lost after treatments were given. Our present attitude is that x-ray therapy seems to be adequate treatment but it is still not a settled question.

DR. REGNIER: Do you consider that x-ray therapy affects the pituitary itself or does radiation of the retrobulbar tissues inhibit the progressive exophthalmos by removing the edema and cellular infiltration in the retrobulbar space?

DR. PEYTON: We admit we cannot irradiate the pituitary alone without irradiating the orbit also. The answer to your question, therefore, is that we don't know.

DR. MARTIN NORDLAND, Minneapolis: These case reports presented so well by Dr. Camp are most interesting and represent one of the most difficult problems related to exophthalmic goiter.

The cause of progressive exophthalmos following operations for toxic goiter has not been fully explained. Various theories, as well as carefully conducted studies along this line, have been reported, but as yet no satisfactory reasons have been established. Classification of recurrent hyperthyroidism can readily be made on the basis of whether the previous removal of the gland was adequate or inadequate, and of course the proper treatment in the latter type of case is prophylaxis. This consists in a thorough removal of the gland, including the isthmus and also the pyramidal lobe if present, leaving only a thin layer on the posterior capsule and taking care to locate and resect any retrotracheal extensions. This procedure will prevent most, but not all, recurrences, and it is in this latter type that one cannot attribute progressive exophthalmos to inadequate or incomplete surgery.

In only a few cases a partial return of some of the signs of hyperthyroidism is present and it is in these cases especially that therapeutic measures fail. In a certain group of cases, exophthalmos, frequently hardly noticeable pre-operatively, becomes more and more progressive following removal of the gland, so that permanent damage seems a likely factor in the production of these changes. The pathologic change responsible for this condition, as described by Naffziger and Jones, is of mechanical origin, and is the result of pronounced swelling of the extraocular muscles to from three to eight times their normal size. They recommend for these cases of progressive exophthalmos following thyroidectomy, decompression by removal of the roofs of the orbit through bilateral frontal bone flap.

As Dr. Camp has pointed out, this procedure was not applicable in these cases.

Dr. A. E. Cardle of Minneapolis then read his Inaugural Thesis on "The Pituitary Gland and Diabetes Mellitus." Lantern slides were shown.

THE IMPORTANCE OF THE PITUITARY GLAND IN DIABETES MELLITUS

A. E. CARDLE, M.D.
Minneapolis, Minnesota

The brilliant work in 1890 by Von Mehring and Minowski, in which they discovered that the complete removal of the pancreas in dog is followed by symptoms which closely resembled human diabetes mellitus, paved the way for one of the greatest discoveries of mankind. This work and the deductions which have come as a result are well known to you all. Years of research finally culminated in the preparation by Banting and Best in 1921 of an active and serviceable pancreatic extract, by the use of which they were not only successful in controlling symptoms in depancreatized animals but in human diabetes mellitus as well.

The isolation of the active principle of insulin as a crystalline entity by Abel and his co-workers in 1926 gave the exact chemical composition and structure of insulin, and finally the discovery by Hagedorn in 1925 of the protamine combination added still another important step in the control of altered carbohydrate metabolism. With the discovery of insulin new interest at once arose in the disease, for now we had a definite therapeutic agent with which to attack the disease and one which gave results. It is still our strongest weapon.

Diabetes is a disturbance of carbohydrate metabolism, and at first it appeared that insulin was the answer to this disturbance. The physiologists, however, are giving us a new viewpoint, and diabetes is no longer regarded wholly as a lack of pancreatic activity but is a disease due to disturbance of endocrine regulation. It would indeed be strange if nature had concentrated the control of such a vital function in one organ. It is more logical to believe that sugar disposal is more carefully safeguarded by multiple mechanisms. This has opened an entirely new field of research of great importance.

Experiments in this field are showing that not only the pancreas, but also the pituitary, the thyroid, adrenal, and even at times the ovaries and testes influence carbohydrate metabolism. A new conception and a broader outlook in the treatment of diabetes mellitus is slowly approaching. Clinically we are recognizing more and more that certain cases of diabetes differ in some respects from the usual type of case. During the past fifteen years I have been working with a large group of diabetics at the Minneapolis General Hospital and it is not an uncommon experience to find patients, under good management, which fail to respond to well established methods of treatment. To explain the cause for this "difficulty in regulation" is not easy, and I am certain that you who treat diabetes have at times been confronted with the same problem. I am sure that in some of these cases this glandular relationship may play a part. To say that it may play a part is one thing but to explain the actual mechanism is another thing.

I wish tonight to discuss one phase of this glandular relationship—i.e., the importance of the pituitary. Of

all the endocrine glands involved in carbohydrate metabolism, and presumably in diabetes mellitus, the most important, exclusive of the pancreas, is the anterior lobe of the pituitary.

To do this I am going to give briefly the results of investigations in this field. This work is chiefly with animals, and as with every new branch of investigation the results are sometimes confusing. However, I believe that certain conclusions are definite, inasmuch as the investigations have been repeated with similar results. From these, certain applications can be made to human diabetes, which help not only in explaining some features of the disease, but may be of great usefulness in treatment.

Experimental Evidence Showing the Importance of the Pituitary Gland

The frequent occurrence of glycosuria in acromegaly and pituitary tumors focussed the attention of investigators upon the relationship of the pituitary to the pancreas, but it remained for Houssay and Magenta in 1925 to first confirm the relationship. They found "that the diabetic symptoms which could be produced in dogs by pancreatectomy were considerably ameliorated by removing the pituitary gland; performed either before or after the removal of the pancreas." In other words, no diabetes, or only a very mild one, will develop where the pituitary has been removed. This work was a remarkable discovery. Since that time these findings have been frequently confirmed, not only in dogs and toads, but also by Long and Lukens in cats. These animals can live in fairly good health for as long as six months without insulin, and as such serve as very sensitive test objects.

Further, studies by Evans has shown that injections of an extract of the anterior pituitary into well-nourished dogs, cats, and rabbits leads to hyperglycemia, glycosuria, polyuria, and ketonuria in from three to seven days. Following injection of the extract into animals there is a gradual fall of insulin content of the pancreas to very low levels, and symptoms of diabetes persist one to three days after cessation of the injection. At its height the condition may simulate in severity that produced by partial pancreatectomy. This pancreas, if examined, will show degranulation and hydropic degeneration of the beta cells of the islets of Langerhans. Degeneration of this kind was common in islets of dogs which were undergoing treatment with the extracts and may be brought about by the strain of sudden induction of the diabetic condition.

Upon cessation of the injections, if the degenerative condition has not been present for too long a period, the insulin content may return to normal. However, if the amount of extract is increased (25 grams of fresh gland daily), the reaction in the pancreas is no longer reversible, and the point is reached where the degeneration in the islets becomes irreversible, so that the diabetes continues indefinitely. We therefor see the following effects produced by the injections of anterior pituitary extract: (1) temporary diabetes—a state produced by a small number of injections with recovery possible when the injections are stopped; and, (2) permanent diabetes—a state produced by more severe

injections from which the pancreas will not recover.

Ham and Haist have reviewed the histology of the pancreas of dogs in various stages of anterior-pituitary induced diabetes: those in temporary diabetes, those recovered from temporary diabetes, and those in permanent condition. They found that "daily injections of this extract led to a progressive degranulation of the beta cells of the islets of Langerhans, and beginning hydropic degeneration, which was almost complete after seven daily injections. If allowed to recover the beta cells recovered about one-half of their granules three days after the last injection. Mitotic figures were also observed in these cases. However, in those dogs in which permanent diabetes developed, granular beta cells became very scarce and there was replacement of the islets by hyaline material." It was interesting to note, at this point, that this latter change may be reflected in certain human beings. Hyaline degeneration of the islets has been noted in about 50 per cent of the persons dying of diabetes. This varies in amounts. Arey, of the University of Minnesota, has noted that it gives the staining reactions of amyloid. However, I have discussed this point personally with Dr. Arey and he states the lesion is not specific for diabetes, nor is there any relation between the clinical severity of the disease and the extent of hyaline replacement of the islets.

These are the experiments that justify the belief that diabetes may not be due only to a lack of insulin by a disordered pancreas per se, but that the production of insulin may be deficient due to the activity of the anterior pituitary gland.

Analysis has shown that the extract of the anterior pituitary contains two important factors: (1) a pancreatropic factor which stimulates the formation of pancreatic islands and increases the amount of insulin; (2) a diabetogenic factor which consists of two parts, glycuric and ketogenic. This latter diabetogenic factor has also been given by other authors the name of contra-insular hormone, and is the hyperglycemizing substance which stimulates decomposition of glycogen in the liver. In passing, however, one must note that the extract does not exert a similar action on the guinea pig, mouse, or rat. In these animals treatment with anterior pituitary extracts can increase both the amount of islet tissue and the amount of insulin found in the pancreas. This is likely due to a preponderance of the pancreatropic effect of pituitary extract, and is, undoubtedly, compensatory and precedes the condition which occurs in dogs.

There are many features as to the probable method of action of the extract—the effect on the liver, etc.—of which time will not permit an explanation. One point seems fairly well established. The diabetogenic factor lies in the anterior lobe and is probably secreted by the eosinophile cells. The only point in question is the directness of the action. Observations by Lucke indicate that the anterior pituitary extract when injected causes a liberation of adrenalin, which in turn leads to insulin antagonism and hyperglycemia. Housay, however, is still of the opinion that the effect is produced directly in the liver, since the removal of

the other glands as well as the adrenals left the chain unaltered. The liver is the only organ necessary for the production of diabetogenic effects by the anterior lobe extract.

To recapitulate, the impression from experimental work seems fairly well established, namely, that there is a distinct antagonism between insulin and the diabetogenic factor of the anterior pituitary.

Clinical Observations Showing the Pituitary Relationship

The more we advance in the knowledge of carbohydrate metabolism and especially as it relates to diabetes mellitus, the more we appreciate that certain clinical findings may be expressions of the pituitary relationship. I wish to enumerate and discuss certain of these clinical findings and show this relationship.

1. *Growth and Weight*.—These simple physical characteristics which often go unnoticed are beginning to be recognized as evidence of importance in the physiology of diabetes. Observations along these lines have produced direct evidence of hypophyseal relationship.

Priscilla White has reviewed the subject in relation to juvenile diabetes, and has included certain data which appear significant. Study of 1,250 patients with juvenile diabetes (onset before the age of fifteen) indicated that 177 showed evidence of pituitary involvement. One hundred seventy-six of these showed involvement of the anterior lobe (9 hyperactivity and 168 hypoactivity). Certain other interesting observations were made in support of her findings.

(a) The age incidence of the onset of juvenile diabetes follows peaks of increasing activity of the pituitary gland. These are about ages six and twelve.

(b) Overgrowth is the most common precursor of juvenile diabetes. Obesity is the most common precursor of diabetes in adults. In adults the most common age group for the development of diabetes is fifty-three years. At this time there is usually an excess of anterior pituitary hormone being produced. This is especially so in women, where an excess of gonadotropic hormone is being produced and excess weight is a common condition. In this connection Young's experiment is very interesting, in that after repeated injections of anterior pituitary extract his dogs became extremely obese prior to the onset of diabetes.

In treating children with the growth hormone it must be kept in mind that one may produce a diabetes through a disturbance of the pituitary. Strauch in 1939 reported a case in a boy seventeen years of age. Six months after the beginning of treatment, violent thirst appeared and he complained of severe exhaustion. Examination revealed sugar and acetone in the urine and a marked elevation of blood sugar value. It was necessary to administer insulin in order to control the condition. The author warns against the indiscriminate use of hormones without strict clinical observation. Also in children hepatomegaly is a complication of diabetes. Inasmuch as it is known that injections of anterior pituitary extract will result in the storage of fat

in the liver we are led to believe in a hormone which controls glycogen metabolism.

2. *Insulin Resistance*.—To those who are familiar with this condition you recognize it at once as one of the difficult problems in the treatment of diabetes. At first the case appears simple enough, but soon we find that it will not respond to ordinary measures of diet and insulin. Instead there is required large doses of insulin out of all proportions to what would appear to be needed. There is a definite insensitivity to the hypoglycemic action of insulin. Many cases require six hundred to one thousand units of insulin a day before the diabetic symptoms are controlled. To date we have had a number of explanations for this phenomenon. These are chiefly infection, allergy, lack of insulin absorption, etc. However, we are beginning to see that the pituitary is likely a factor in a number of these cases. This subject has been splendidly reviewed in a recent article by Martin, Leister, and Strouse. They tabulated in detail not only their own cases, but also many others which they could find in the literature, in an attempt to ascertain the cause of the resistance. A definite pituitary influence was found in many of their cases. Not all insulin resistance cases are due to this, but the activity of the anterior lobe is undoubtedly an extrapancreatic factor. The experiment of De Wesselow and Griffiths is interesting in this respect. They found that the plasma of a certain type of diabetic patient contains an extract of the anterior pituitary. The administration of such plasma to a fasting rabbit results in a depression of the animal's sensitivity to the hypoglycemic action of administered insulin. This experiment lacks confirmation, but it is very suggestive.

3. *Ketosis*.—It has been assumed to date that the development of ketosis is an alteration of fat metabolism associated with altered carbohydrate metabolism. However, it has been shown that the urinary excretions of acetone bodies by fasting or fat-fed rats, normally quite small, may be gradually increased by the injection of anterior pituitary extracts, and there is a similar rise in blood ketones, which is a more sensitive and dependable index of the phenomenon, since acetone and diacetic acid are threshold substances. There is good evidence to show that there is an increased outpouring of ketone bodies by the liver, rather than a diminished utilization of them; and in general the ketosis is accompanied by a transfer of fats from the depots to the liver, in which large quantities may accumulate. This is an important observation.

This stimulation is likely produced by the aforementioned ketogenic part of the diabetogenic factor. There are some confusing statements which arise in regard to this particular point, but it would appear that a new understanding of ketosis is arising which will help greatly in understanding the mechanism.

4. *Dietary Management*.—To date there has been considerable controversy regarding the type of diet which is best in the management of the diabetic. We have gone through the period of high-fat and high-

carbohydrate diet. Most everyone now has agreed upon a middle ground. However, experiments involving the pituitary are beginning to give us a better understanding as to how the type of diet may be of value in the course of the disease. Best, Ribaut, and Haist found in rats that the change in the islet cells which is produced by the injection of anterior pituitary extract, could be prevented by fasting or the feeding of a diet of fat. At the same time there is a definite reduction in the insulin content of the pancreas. On the other hand animals fed on a diet high in sugar content show a marked increase in the insulin content of the pancreas, which is due to an overactivity of the cells.

The importance of this observation, of course, is that a pancreas which is being permitted to rest by dietary measures or by insulin will be saved from degenerative changes. Fasting, fat diets, or insulin inhibit the action of the anterior pituitary and thus prevent the onset of diabetes. If the clinician is convinced that stimulation of the pancreas is necessary, diets rich in carbohydrate and the use of insulin are indicated; but if he believes the pancreas should be rested then the use of fasting, fat feeding, and insulin is desirable. These are important points, and more work should be done along these lines.

5. *Hyperinsulinism*.—Here is a disorder which is the antithesis of what has been presented so far, and is included under this heading inasmuch as it would seem to be definitely associated at times with a pituitary disorder. Practically, this would be one of our best therapeutic approaches to this disease; namely, that an active anterior pituitary would be important in the control of the disease, inasmuch as we wish to reduce the activity of the pancreas. Granted that the case of adenoma might be an exception, the cases of hypertrophy and hyperplasia of the pancreas would seem to present excellent material. This field is entirely new, and there has been very little work along this point, but the application must be kept in mind as one comes in contact with these cases.

There are many other points which might be raised to show the pituitary relationship besides the ones that I have just mentioned. Undoubtedly the pituitary gland plays a part in the pregnant diabetic. It has been thought in the past that the variations in the mother's tolerance was due entirely to the compensatory part played by the pancreas of the fetus. However, in view of the fact that many cases of diabetes in pregnancy are helped by the use of various glandular substances, the effect of these is probably through the medium of the pituitary. At the present time studies along this line are being made, and as our laboratory methods improve we can expect much light to be thrown upon this field. A suggestion has been made that the effect of fever on carbohydrate metabolism may be explained through the action of the pituitary. Zondek and Katz have made some studies in both of these fields, but their conclusions are somewhat indefinite.

All of the points enumerated, I believe, are significant

in showing that there is clinically a definite pituitary influence exerted in diabetes mellitus.

The Significance of the Anterior Pituitary to Human Diabetes

The natural outcome of experiments of Houssay, Evans, and Young has been an attempt to correlate their findings with clinical application. The fact that pancreatectomy in dogs produces diabetes, which could be relieved by insulin, and the finding of islet lesions in many cases of human diabetes led to the view that diabetes was a disease of the pancreas *per se*. The recent work which has just been described showing that the same changes in the pancreas could be produced by pituitary extract has somewhat modified this view.

No doubt human diabetes can result from lesions of the islets due to pituitary origin, and very likely certain changes are taking place in the human pancreas depending upon the severity of the action. Whether or not changes in the human pancreas are similar to those which take place in the dog cannot as yet be proved. The fact that changes cannot be found in many human beings dying of diabetes does not disprove this theory, inasmuch as the material is not examined immediately and to date proper stains have not been used. Also human diabetes usually runs a slower course and the breakdown of the beta cells is so gradual that the discovery of an occasional cell in degeneration is uncommon.

We know that the activity of the pituitary must vary from time to time since our cases of diabetes vary in activity from time to time. Take, for instance, a human patient with very mild diabetes and very obese. Reducing this diabetic may improve the tolerance which will eliminate the disease and possibly make the patient non-diabetic. Also, we know that the action of the sex hormones, which have a definite relationship to the pituitary, vary from time to time. It is conceivable that short periods of hyperactivity of the pituitary might result in liberation of varying amounts of diabetogenic substance which might produce temporary changes or permanent changes.

Ham and Haist believe that "diabetes is due, not to a decrease in a fixed production of insulin, but rather to an increase in the ratio of insulin need to insulin production. The anterior pituitary stimulates the pancreas to excessive function, causing cellular degeneration. The extract acts on the tissues and organs, other than the pancreas, increasing the need for insulin; and it also exerts a trophic effect on the pancreas causing the cells to secrete at a high rate. The early stages of diabetes produced by anterior pituitary extract can be explained by increase need for insulin; the latter stages (permanent diabetes) by diminished production. The diabetes due to increased need will lead to exhaustion of the pancreatic cells."

Clinically, of course, we need in some way to inhibit the activity of the anterior pituitary. A number of attempts have been made to do this. Radiation has been tried without any apparent success. Surgical removal of the pituitary was reported by Chabanier. A successful hypophysectomy was performed which definitely

decreased the amount of insulin needed for treatment. Unfortunately, the boy developed tuberculosis and died, but it does show results from an heroic piece of surgery. It has been definitely shown that injection of estrogenic substances at the time of menopause in diabetics will inhibit the excessive production of the diabetogenic factor and cause a diminution in the insulin requirement. This has been shown repeatedly and, of course, has a definite practical importance in the treatment of diabetics at the time of menopause. There is some proof that androgen treatment will have a similar result in males, but the cases are too few to draw any conclusions.

The importance of recognizing therapy in this direction is not only for the treatment of the disease itself, but for the possible prevention, which is a matter of great importance. The use of insulin alone will not prevent the disease, but if a clear understanding can be had as to the actual relationship of the pituitary we may be able to make strides in this direction. Best et al. have shown that "diabetes can be prevented in a dog receiving injections of anterior pituitary extract, provided simultaneously insulin is administered." This for the first time raises the possibility of a method by which diabetes can be attacked and stopped in its early stages and even avoided by prophylactic means. One further experiment is notable. Depancreatized dogs show a marked decrease in glycosuria when given extra-peritoneal injections of serum from other dogs treated over several months with anterior pituitary extract. This serves the function of an antifactor which is antagonistic to the anterior pituitary.

Case Report

It is at this point that I would like to report briefly a case of my own. I realize that the results and impressions are open to criticism, inasmuch as it was a private case and the observations could not be continued over any length of time, but I believe they are significant enough to show a possible practical application along these lines.

A thirty-five-year-old white man was admitted to Abbott Hospital on May 14, 1941. He stated that he had been well until the spring of 1939, at which time he developed sweating, trembling of the hands, and emotional instability. These symptoms appeared in an attack-like manner, and on two occasions he collapsed without losing consciousness. He was seen through the summer of 1939 in a clinic where a diagnosis of hypoglycemia was made. He was placed upon dietary management and was fairly well controlled until October 14, 1940, when he developed periodic seizures of a similar nature which could not be controlled by dietary means. I first saw him in May, 1941. He was sent to the hospital for the purpose of study and to see whether or not something might be done to help him. General physical examination was negative. The blood pressure was 120/80. There was no suggestion of abnormality in the adipose distribution. The urine examination was negative. The hemoglobin was 83 per cent, and the white count was 6,800. A glucose tolerance test revealed the following:

Fasting—71 mg.
30 minutes—133 mg.
1 hour—90 mg.
2 hours—69 mg.
2½ hours—59 mg.

Simultaneously venous and arterial blood sugars showed 90 and 112, respectively, with a capillary blood sugar loss of 22 mgs. Basal metabolism was normal. The patient was placed upon a diet and was given a course of polyansyn, which is the extract of the anterior pituitary gland and which is shown to have the diabetogenic factor included. After a week's treatment with this drug a glucose tolerance test was as follows:

Fasting—100 mg.
30 minutes—133 mg.
1 hour—102 mg.
2 hours—66 mg.
2½ hours—90 mg.

You can see from these observations that there appears to be a definite rise in the blood sugar. These were the only observations I was able to make, inasmuch as the patient was very actively interested in some operative procedure. He was accordingly advised that a condition in the pancreas existed, the type not exactly known, and that exploration was suggested. The mortality of this was explained to him and it was suggested that I preferred keeping him upon medical treatment. However, he insisted upon the operative procedure. Accordingly, he was referred to a surgeon for section. An adequate exposure of the pancreas was accomplished, and when it was exposed here was found to be a hypertrophy of the gland. There were no adenomatous changes. Therefore, a resection of the gland was attempted. During the course of the resection such extensive bleeding was encountered that it was necessary to stop, pack the wound, and take the patient back to his room. He died on the sixteenth postoperative day, because of a sudden abdominal hemorrhage. Autopsy revealed a pancreas which weighed 126 grams. There was no tumor which could be detected, and the pathologist reported hypertrophy of the pancreas. Death was due to a traumatic hemorrhage from the splenic artery. This case, unfortunately for the surgeon, ended in a catastrophe, and if it had not been for the insistence of the patient in electing surgery, the step might not have been taken. However, be that as it may, it is my purpose in reporting this to bring out what does seem to be a definite antagonism in these glands, the reverse of those found in diabetes mellitus, in order that a more direct relationship of the pituitary might be shown.

Thus I wish again to emphasize that we are approaching a new era in our understanding of this disease. The results of the experiments and the practical applications, though meagre as yet, show definite progress in the right direction. The pituitary gland, I still believe, is the most important gland of all, as it affects carbohydrate metabolism. If we are to progress in the amelioration of this disease, we must be constantly on the alert for new signs and symptoms of pituitary activity.

Summary

1. A review of the literature proves that experimentally there is a definite relationship between the pituitary and the pancreas in diabetes mellitus.
2. The anterior lobe of the pituitary is the active factor in this relationship, and the action is antagonistic to the pancreas.
3. Certain observations are given which show the importance of recognizing the activity of the anterior pituitary, clinically.
4. Points in clinical application are presented and discussed, together with a personal case report, to show

the possibilities in the ever-widening field of diabetes mellitus.

5. If progress is to be made in the treatment of diabetes mellitus we must be on the alert to recognize the influence of the pituitary. It may be possible to alleviate the disease and it is hoped that the disease may actually be prevented.

In closing, I wish to quote from Joslyn's Memorial Address for Banting, presented before the American Diabetes Association:

"In the pituitary gland there is a hormone, not yet isolated, which injected into a dog will cause diabetes, but with each injection until the last massive dose there is a struggle for reversal of the process. There must be something like an antidiabetic hormone. Which one of you will discover it?"

Discussion

DR. C. B. DRAKE, Saint Paul: One phase of the subject which Dr. Cardle mentioned is the glycosuria occasionally associated with pregnancy. I have never heard a satisfactory explanation of this finding but have thought it probably is associated with the change we know occurs in the pituitary during pregnancy. The enlargement of the pituitary at such times is sufficient to produce a demonstrable contraction in the visual fields. Presumably the enlargement is accompanied by an increased secretion, which might affect the sugar metabolism.

I have observed a woman who during three successive pregnancies ran glucose in her urine in considerable amounts which disappeared upon delivery. The glucose tolerance test was normal, which showed the kidney threshold to be reduced. No dietary control was adopted and no difficulty encountered. The pituitary effect, if that is what causes this condition, is not identical then with the condition known as diabetes mellitus.

I wonder whether Dr. Cardle has any additional ideas on this particular phase of the subject.

DR. MOSES BARRON, Minneapolis: There is no doubt from the clinical standpoint that the pancreas is the most important site for controlling sugar metabolism, but the work of Soskin of the Michael Reese Hospital seems to show that the liver plays a very important part in diabetes. The more recent work seems to show that, contrary to previous teaching, the fats do not burn in the flame of carbohydrate metabolism.

I would like to ask Dr. Cardle a question relative to the case he presented. He mentioned that at the autopsy there was a hypertrophy of the pancreas. Normally the pancreas varies a great deal in weight and it is difficult to decide when there is hypertrophy. Did the microscopic sections show hypertrophy and was there definite hyperplasia of the islands of Langerhans? In hypertrophy, there is more of an increase in the external secretory cells.

The meeting adjourned.

E. V. KENEFICK, M.D.

Secretary

ESOPHAGEAL PERFORATION FROM A STOMACH TUBE

(Continued from Page 280)

and the fascia lateral to the sternohyoid muscle divided to expose the carotid sheath and thyroid gland. The thyroid was retracted medially and the carotid laterally, thus exposing the trachea and esophagus. The dissection was then carried downward behind the esophagus, into the retrovisceral space. In this last procedure care was exercised to avoid injury to the inferior thyroid artery and recurrent laryngeal nerve. On entering the retrovisceral space, material which had escaped from the esophagus was immediately encountered. In this material were small pieces of chicken from her dinner the previous evening. The perforation was posterior and slightly to the left at about the level of the fifth cervical vertebra. The perforation was large enough to admit the tip of the little finger. The tip of the finger was held in the opening while the area below and about was cleaned out. Then iodoform gauze was packed loosely into the space below the opening and brought up and out through the wound. A small piece of rubber tissue was also brought out through the wound and the wound was sutured about these. No attempt was made to close the perforation in the esophagus.

At the time of operation the patient had a temperature of 101 degrees and a leukocyte count of over 14,000. The temperature rose to about 103° after the operation and the leukocyte count rose somewhat during the next two or three days, but both the temperature and the leukocyte count gradually came down to normal in about one week.

The patient was given intravenous glucose for about three days, but then was able to get enough food by mouth. During the first week after the operation considerable of the food came through the sinus. Some discharge continued for from six to eight weeks. The patient has been practically normal since.

Sulfanilamide in the wound and postoperatively was, no doubt, an important factor in reducing the virulence of the infection.

The nearest approach to this case which I have found reported was that of Snyder of Miami. In his case a probang was used to dislodge the material in the esophagus. Operation was not carried out until three days after the accident. Considerable discussion has appeared in the literature as to the treatment of perforations of the esophagus. Some advise treating them conservatively while others are emphatic in advising early operation. Many patients with slowly perforating or minute perforations have recovered without resorting to surgery, but large, immediate perforations of this type are surgical emergencies. The earlier operation is done, the better are the chances of the patient's recovery.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR APRIL

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth. Speaker: William A. O'Brien, M.D., Director of Postgraduate Medical Education, Medical School, University of Minnesota.

April 4—Progress in Cancer Control

April 11—Cancer of Breast

April 18—Cancer Diagnosis

April 25—Tumors of Mouth

WAR SESSIONS OF THE AMERICAN COLLEGE OF SURGEONS

During March and April a number of one-day "War Sessions" on problems of military service and civilian defense for medical and hospital personnel have been and are being held by the American College of Surgeons in cities throughout the country. On May 1 such a meeting will be held at the Radisson Hotel in Minneapolis.

The meetings open at 9:00 a.m. with panel discussions on treatment of war injuries for the medical profession and a forum on civilian defense as related to hospitals, led by a medical officer of the United States Office of Civilian Defense, for hospital personnel. From 10:45 to noon a joint meeting for physicians, surgeons and hospital representatives is held, with medical officers of the United States Army, the United States Navy, and the Office of Civilian Defense, as speakers. At the joint luncheon which follows, the Procurement and Assignment Service in relation to the medical profession and to hospitals, is discussed by Major Sam F. Seeley, Executive Officer, a specially appointed delegate. In the afternoon, panel discussions for the medical profession are held on treatment of wounds of soft parts and on fractures, and for hospital representatives on special problems incident to the war as affecting hospitals.

The dinner meeting and the panel discussions which follow, on treatment of burns and prevention and treatment of shock, are for the entire group. The representatives of the army and the navy medical corps collaborate with civilian surgeons in leading these discussions.

Hospital representatives and the medical profession in the participating states took advantage in considerable numbers of the opportunity afforded them at the meetings held in March, to obtain direct authoritative information on the meeting of war responsibilities by workers in the health field. The success of these meetings justified their extension to the remaining states as shown by the April schedule. Hospital associations and state and county medical societies are coöperating with the American College of Surgeons in conducting the sessions.

AMERICAN FEDERATION FOR CLINICAL RESEARCH

The second annual meeting of the American Federation for Clinical Research will be conducted at the Center for Continuation Study on the University of Minnesota campus, April 20-21.

The program for the meeting will consist of reports on original research investigation by members. There will be a dinner Monday evening.

Dr. Richard L. Varco is local chairman of the program committee. He is being assisted by members of the executive committee of the Clinical Research Club, University Hospitals: Dr. Charles E. McLennan, Dr. John A. Anderson, Dr. Olaf Mickelsen, Dr. Clarence Dennis and Dr. F. W. Hoffbauer. The latter is chairman of the local clinical society.

Membership in the society is limited to younger men and former members of clinical hospital staffs who have done original clinical research acceptable to the executive committee.

Dr. Maurice Schnitker of Toledo is president of the federation, and will preside at the meeting.

GEORGE CHASE CHRISTIAN LECTURE

Dr. H. B. Andervont, principal biologist with the National Cancer Institute of the National Institute of Health, United States Public Health Service, will present the annual George Chase Christian lecture on Wednesday evening, April 15, in the Medical Science Amphitheater, University of Minnesota Medical School. His subject will be "Recent Trends in Cancer Research."

INTERPROFESSIONAL MEETING

Physicians, dentists, druggists and nurses from ten surrounding counties will meet at an interprofessional dinner to be held at the St. Cloud Hotel, St. Cloud, April 23. The meeting is under the sponsorship of the Committee on Interprofessional Relationships, of which Dr. F. J. Savage of Saint Paul is chairman. Speakers will be Dr. P. F. Meyer of Faribault and Dr. Carl Johnson of Dawson. They will discuss rural nursing problems. Tickets are \$1.00.

STATE MEETING

A program of great interest and variety has been arranged by the Committee on Scientific Assembly for the 89th annual meeting of the Minnesota State Medical Association which is scheduled for Monday, Tuesday and Wednesday, June 29, 30 and July 1, at the newly remodelled Armory in Duluth.

Symposia, demonstrations and conferences will occupy the first half of each morning program and there will be special afternoon discussion on subjects of importance to the war effort in addition to the regular scientific program.

A clinical-pathological conference will start the day's schedule on Monday, with symposia on therapeutics and emergency surgery on Tuesday and Wednesday mornings.

There will be a demonstration of Sister Kenny's method on Monday morning, also. On Monday afternoon a three-cornered discussion on virus diseases in man, in animals and in plants will share attention with an obstetrical demonstration. On Tuesday morning there will be a conference and demonstration on blood plasma and transfusion to share the spotlight with the session on therapeutics. Tuesday afternoon will be devoted to scientific papers including the annual Russell D. Carman Lecture in radiology and also a special nutrition conference at which Dr. Julian Boyd of the Children's Hospital in Iowa City will be guest speaker.

On Wednesday morning there will be a tuberculosis conference in addition to the symposium on emergency surgery as well as clinics at Duluth hospitals arranged by the Academy on Ophthalmology and Otolaryngology. In the afternoon there will be an industrial health and safety conference to which shop managers, safety superintendents and others interested in industrial health will be invited. At the same time, the Academy will hold a special scientific meeting of its own. Guest speakers for this session, Drs. G. H. Haessler of Milwaukee and J. R. Lindsay of Chicago, will appear under Academy sponsorship on the general program Wednesday morning.

Among other out-of-state guests will be Dr. A. J. Carlson of Chicago, Dr. A. J. Quick of Milwaukee, Dr. F. W. Rankin of Lexington, Ky., president of the American Medical Association, and Dr. Arthur C. Christie of Washington, D. C., who will deliver the Carman lecture. Round-table luncheons will feature the first two days of the meeting. The social program will include an entertainment Monday night at the Northland Country Club and the banquet, Tuesday night, at the Hotel Duluth.

THE MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club in Saint Paul, Tuesday, March 10, 1942. Dinner was served at 6:30 p.m.

The following program was presented:

1. A Clinical Evaluation of Electro-shock Therapy, One Hundred Cases (Inaugural Thesis)
HENRY HUTCHINSON, M.D.
Moose Lake
2. Complexities Concerning Criminal Responsibility
J. C. MICHAEL, M.D.
Minneapolis
W. L. PATTERSON, M.D.
Fergus Falls
3. Lupus Erythematosus Disseminatus, Neurological Findings. (Illustrated with colored motion pictures and slides, pathological demonstrations.)
MAURICE N. WALSH, M.D.
Rochester

MINNESOTA PATHOLOGICAL SOCIETY

When the Minnesota Pathological Society meets April 7, members will hear a paper by Dr. Alvin F. Coburn of Columbia University, New York. Dr. Coburn's subject will be "The Rôle of Hemolytic Streptococcus in the Pathogenesis of Rheumatic Fever."

RED RIVER VALLEY MEDICAL SOCIETY

The midwinter meeting of the Red River Valley Medical Society was held February 19 at Crookston.

Dr. Theodore H. Sweetser of Minneapolis presented a paper, "Injuries and Wounds of the Urinary Tracts," at the medical meeting which followed the dinner at the Hotel Crookston. Dr. W. W. Burnap of Fergus Falls discussed the plan for procurement of physicians for Army service.

SAINT PAUL SURGICAL SOCIETY

A symposium on poliomyelitis will be held at the meeting of the Saint Paul Surgical Society, April 9, at the University Club. The symposium at 7:30 p.m. will be preceded by a dinner at 6:15 p.m.

Appearing by invitation, Dr. Miland E. Knapp of Minneapolis will present a paper on "The Kenny Technique for Treatment of Infantile Paralysis." Dr. Wallace Cole of Saint Paul will discuss the surgical aspects of poliomyelitis.

SCOTT-CARVER SOCIETY

The Scott-Carver Medical Society met at Shakopee on February 17, 1942. Dr. Owen Robbins of Minneapolis spoke on the subject of "Sterility."

STEELE COUNTY MEDICAL SOCIETY

Dr. D. E. Morehead of Owatonna was elected president of the Steele County Medical Society at its annual dinner meeting last month.

Other officers named were Dr. T. W. Stransky, vice president; Dr. R. J. Wilkowske, secretary-treasurer; and Dr. D. H. Dewey, censor for a three-year term. Dr. A. B. Stewart was appointed county representative to the state committee for procurement and assignment.

It was moved and unanimously voted that each member of the society pledge himself to the purchase of at least one defense bond each month.

WASHINGTON COUNTY MEDICAL SOCIETY

The regular meeting of the Washington County Medical Society was held March 10 at Stillwater.

Considerable time was devoted to the Officers' Meeting on February 28, discussion of which was very lively. The Procurement Service questionnaire was discussed at length.

The scientific program was devoted to a colored movie, "Regional Anesthesia," in four reels. These moving pictures in all probability will solve a lot of the questions of scientific programs for many small county societies. The Washington County Medical Society finds the pictures very interesting and instructive.

In Memoriam

Ottul Klaranus Lindboe

Dr. O. K. Lindboe of Lac qui Parle, Minnesota, died on February 5, 1942, at the age of ninety, following a three weeks' illness.

Dr. Lindboe was born at Kongsberg, Norway, November 16, 1851. He attended grade and high school there and night school in Christiania (now Oslo), working during the day to pay his way. His father died when Dr. Lindboe was a small boy but his mother, who was also a doctor, brought her son to America when he was sixteen. After an eight weeks' ocean voyage they landed at Quebec. They traveled on cattle cars to Detroit and then took a boat to Chicago.

In 1868 the doctor started for Colorado with an uncle in search of gold. Having made a stake of about \$5,000 during the year, he and his uncle set out on their return trip to Chicago. Carrying his belongings in a knapsack and sleeping out of doors, the young man awoke one morning to find he had been robbed of his fortune. After doing odd jobs for a time in Chicago he again set out for the West, but again met with misfortune, the party being attacked by Indians. The fight continued for nine days and the party was forced to live on mule meat. The doctor carried the scars of a bullet wound in a leg and an arrow wound in his back.

Returning to Chicago, Dr. Lindboe took a course in pharmacy and later attended Rush Medical College, where he received his medical degree in 1877. For two years he practiced in Illinois, Michigan, and in several Minnesota towns before going to Montevideo in 1879. The same year he married Anna Christine Johnson at Beloit, Wisconsin, and then moved to Lac qui Parle. Except for a few years when he lived in the town of Lac qui Parle, Dr. Lindboe made his home on his farm.

During his residence in the Lac qui Parle community, Dr. Lindboe served for more than thirty years on the school board and for many years on the town and health boards. He was a member of the Riverside Sanatorium board for a number of years but resigned last summer because of failing vision.

Mrs. Lindboe died in 1928. Dr. Lindboe is survived by a son, Andrew, of Minneapolis and three daughters, Mrs. Joe Anthony and Elsie of Lac qui Parle and Mrs. Robert Dahl of Dawson. One daughter, Ella, preceded him in death.

Charles F. McNevin

Dr. Charles F. McNevin of Saint Paul died at St. Joseph's Hospital, February 16, 1942, following an intermittent illness of about two years.

Dr. McNevin was born February 19, 1877, at Cresco, Iowa, the son of George McNevin and Rose McConville McNevin. His parents died when he was very young and he moved to Lawler, Iowa, where he re-

PICTURE OF A PATIENT WITH *Pharyngitis*

When your patients with pharyngitis, tonsillitis or aphthae complain of feeling as if they had swallowed a sword, NUPORALS, "Ciba," offer quick relief. Containing the well-known anesthetic, Nupercaine* (*a* — butyloxychinchonic acid diethylethylenediamide hydrochloride), these lozenges produce a prolonged local anesthesia of the mucous membranes of the oral cavity and throat when dissolved in the mouth.

Further suggested uses for NUPORALS* include facilitating pharyngeal and laryngeal examinations, easing the passage of a stomach tube, curtailing pain induced by denture irritation or surgical trauma.

NUPORALS

BOXES OF 15

BOTTLES OF 100

*Trade Mark Reg. U. S. Pat. Off. The word "Nuporcis" identifies throat lozenges of Ciba's manufacture, each lozenge contains one mgm. of Nupercaine, "Ciba."

CIBA PHARMACEUTICAL PRODUCTS, INC.
Summit New Jersey

sided with an uncle and aunt. His early education was attained at Lawler. He received the degrees of Bachelor of Science in 1896, Master of Science in 1899, and a Master of Arts in 1901, all from Upper Iowa University. He thereafter took special graduate work at the University of Wisconsin.

Following his graduation at Upper Iowa University, he was superintendent of schools successively in Elkport, Clermont and Ossian, Iowa, and Graceville, Minnesota. He attained the degree of Doctor of Medicine from Northwestern University, Chicago, Illinois, in 1908.

He served a temporary period as intern at Mercy Hospital, Chicago. He entered the Mayo Clinic at Rochester, Minnesota, on June 18, 1908, and was an intern in St. Mary's Hospital for one year and a surgical assistant for fifteen months. He left the Mayo Clinic September 10, 1910, and entered into the practice of medicine and surgery at Saint Paul, Minnesota, where he practiced until his death.

In 1915 he married Abigail Warner Jones, whom he survived by seven years. No children were born of this marriage.

Dr. McNevin, at the time of his passing, was a member of the Board of Trustees of his Alma Mater, Upper Iowa University. Since 1940 he served as a member of the Board of Public Welfare for the City of Saint Paul and Ramsey County. He was a member of the Ramsey County Medical Society, American Medical Association, and the Alumni Association of the Mayo Founda-

tion. He served in the World War I as a captain in the Medical Corps.

His congenial personality endeared him to a host of friends, and his kind ministrations made him deeply beloved by all his patients. He freely gave of his time and skill to those who came to him in need of surgical or medical care.

No physician was more devoted to his patients, but when away from his professional duties he had a fine sense of humor that was greatly appreciated by all who knew him. He had a particular fondness and love of children, and they reciprocated by genuine response to his delightful personality.

He is survived by his brother-in-law, F. A. O'Connor of Dubuque, Iowa, and two nephews Charles E. O'Connor of Washington, D. C., and Francis J. O'Connor of Dubuque, Iowa.

J. M. CULLIGAN, M.D.

Benzedrine, which has received a reputation as a pep-producer, has been found to have practically no effect upon the activity of the sloth.

Self-disinfecting drinking glasses are under study at the California Institute of Technology—the rims are coated with plastic-silver mixture said to kill practically all liquid-borne bacteria.

*"This is the way
to feel refreshed"*

Pause at the familiar red cooler for ice-cold Coca-Cola. Its life, sparkle and delicious taste will give you the real meaning of *refreshment*.

WOMAN'S AUXILIARY

MRS. JOHN J. RYAN, *President*

Saint Paul, Minnesota

MRS. L. R. BOIES, *Publicity Chairman*

Knollwood, Hopkins, Minnesota

East Central

The February meeting of the East Central Counties was held at the home of Mrs. L. Hedenstrom at Cambridge, Minnesota, on the 17th. Mrs. David Gavis, Princeton, was appointed Public Relations chairman. Most of the members are busy with local Red Cross knitting and some of the women are teaching Home Nursing Courses.

Renville

On February 8, Renville County Auxiliary held its regular monthly meeting at Olivia, Minnesota. Very interesting pictures of big game hunting in Canada and Alaska were shown by Dr. J. Cole of Redwood Falls.

Sincere sympathy from all members of the Auxiliary is extended to Dr. F. W. Penhall and family of Morton, in the death of Mrs. Penhall, February 9, 1942. Mrs. Penhall was a charter member of the County Auxiliary and was held in high esteem not only by this group, but by the community at large.

Goodhue

Mrs. E. M. Baldigo, Red Wing, Minnesota, opened her home to members of Goodhue County Medical Auxiliary, February 10. Mrs. E. H. Juers presented some very interesting material on the use of puppet shows in teaching rural children the needs and reasons for vaccination and inoculations.

Recently, five Auxiliary members including Mesdames E. M. Baldigo, R. V. Sherman, R. B. Graves, G. C. Kimmel, and E. H. Juers presented such a puppet show at an evening meeting of the Hay Creek 4-H Club. It was the highlight of the evening! Much credit goes to Goodhue Auxiliary, a new group, for planning such an interesting and unique project!

Hennepin

Hennepin members have had another busy month. On the evening of February 24, a Red Cross Benefit party was given in the Medical Assembly of the Medical Arts Building. A gay nineties show was the theme of the program. Clever numbers by the Auxiliary Octet under the direction of Mrs. Gilbert Seashore were introduced by Mrs. Ralph Knight. Assisting the octet and prominent in parts were Mmes. J. M. Hall, Horace Newhart, L. S. Arling, Malvin Nydahl, Harvey Nelson, W. J. Brynes, C. A. McKinlay, Joe Neale, J. S. Reynolds, and Drs. Annette Stenstrom and Erling Hanson. Minor parts were taken by Mmes. Elmer Lundquist, Wallace Beckman, and Ralph Creighton. The octet included Mmes. A. N. Russeth, W. R. Jones, R. H. Lindquist, Leo Fink, T. H. Sweetser, K. W. Anderson, E. T. W. Boquist. The musical accompaniment was furnished by the "be-wigged and be-moustached" orchestra which included Drs. Paul Giessler, Lewis Daniel, R. T. LaVake, A. E. Cardle, and F. H. Schaaf.

The last, but by no means the least humorous, part of the program was a "take-off" on the ladies' entertainment and was produced by a men's octet in women's costumes, also of the gay nineties period. The following performed and sang in this group: Drs. E. G. Oppen, R. O. Quello, Elmer Lundquist, C. G. Arvidson, H. F. Wahlquist, Ralph Knight, Malvin Nydahl, and Roger Hallin. Delightful color for a "Mammy" song was furnished by two unusually corpulent Negroes played by Mmes. A. A. Wohlrabe, and Reuben Erickson. The audience enjoyed the program thoroughly, and no doubt the actors and actresses had some fun, too.

Following the entertainment, light refreshments were served by the social chairman, Mrs. John Curtin, and her committee. Mrs. Harold Wahlquist acted as general chairman of the party and Mrs. Frank Bryant as ticket chairman.

On March 6, seventy-five members of the Auxiliary heard Dr. Emilio Le Forte, University of Minnesota, speak on "Our Neighbors to the South." Following the meeting, Mrs. J. C. Davis assisted by Mmes. Herman Drill and Willis Thompson, served tea. Hostesses for the day were Mrs. L. J. Leonard and Mrs. L. K. Buzzelle.

St. Louis

Mrs. P. S. Rudie, Duluth, president of St. Louis County Auxiliary, has moved with her family to Bremerton, Washington, to be with her husband, who is attached to the Naval Base Hospital there. Mrs. H. J. Bianco, Duluth, is now acting president of the Auxiliary.

Ramsey

Many Ramsey County Auxiliary members are working hard in their very successful Red Cross Unit. Others are busy planning two important teas to be given in April. One, the Auxiliary Public Relations Tea, will take place April 27. At the time of the meeting of the American College of Physicians to be held in Saint Paul, April 21-25, the Auxiliary with the Women's Entertainment Committee of that group will give a joint tea. Mrs. E. V. Goltz, Saint Paul, is general chairman of the entertainment committee for the wives of the visiting doctors coming to the city at the time of the meeting.

Mrs. J. A. Cosgriff, Olivia, chairman of *Hygeia*, is to be commended on a fine piece of work. Recently, a check for \$221.25 was received from the State Medical Association in payment for *Hygeia* subscriptions for all State Senators and Representatives.

The State Medical Association convention is to be held in Duluth, June 29, 30 and July 1, 1942. Why not plan, now, to be there?

In a few more months the members of the Woman's Auxiliary of the American Medical Association will be arriving in Atlantic City, New Jersey, for their annual convention, June 8-12. Have you made your reservations? If not, send your request *at once* to Haddon Hall, Atlantic City, New Jersey.

Dr. E. T. W. Boquist of Minneapolis, former fifth district American Legion commander, has been elected chief medical officer of the Minnesota Soldiers Home by the board of directors. He succeeds Dr. Oliver R. Bryant who resigned recently after nine years as chief medical officer.

The appointment of Dr. Boquist, a graduate of the University of Minnesota Medical School, was effective April 1. Dr. Boquist is a member of the staff of Swedish Hospital.

Dr. Edward Dyer Anderson, Minneapolis child specialist and an associate of Dr. Max Seham for fifteen years, has been named a lieutenant commander in the United States Navy.

Dr. Anderson, who volunteered his services as a medical specialist, reported to Washington March 18, and is assigned to the navy dispensary.

Mrs. Anderson will join her husband in Washington.

* * *

Guest speakers at the ninety-first annual session of the Iowa State Medical Society to be held in Des Moines, April 15-17, will include Dr. John L. McKelvey of Minneapolis, head of the department of obstetrics and gynecology, University of Minnesota Medical School, and Dr. James T. Priestley of Rochester.

Dr. McKelvey's subject will be "Cesarean Section," and Dr. Priestley's, "Carcinoma of the Stomach."

* * *

Drs. Lee, Westby and Westby last month moved into their new clinic building in Madison, Minnesota. A modern, well-arranged brick structure, the Madison Clinic is 42 x 52 feet and is divided into thirteen rooms. The waiting room has a seating capacity of twenty-five people.

Dr. Nels Westby and Dr. W. N. Lee have been associated in practice since 1915. They were joined in 1927 by Dr. Magnus Westby.

* * *

Cancer statistics for Minnesota show a steady yearly increase in the number of deaths, according to Dr. W. A. O'Brien, president of the Minnesota Society for the Control of Cancer. In 1910 there were 1,532 deaths, while in 1940 there were 3,767. These facts revealed a circumstance peculiar to Minnesota alone—that in 1940, 53 per cent of the deaths were males and 47 per cent, females. Although the disease occurred in all age groups, it took its greatest toll among those forty-five to seventy-four years of age.

* * *

Among charter members of the newly organized American Gastroscopic Club are Dr. James B. Carey of Minneapolis and Dr. Herman J. Moersch of Rochester. In the society's objectives, emphasis is placed on the fact that the gastroscope should be an instrument used by internists and surgeons and not by technical specialists.

Applicants for membership must have adequate training in internal medicine, gastro-enterology or surgery; they must be members of a scientific organization of high standard or they must be certified by the boards of internal medicine, gastro-enterology or surgery, and they must be recommended by two active members.

* * *

The first course of instruction in the Kenny method for medical directors of physiotherapy training schools was presented at the Center for Continuation Study on the University of Minnesota campus, March 28-April 2.

This will be followed by other courses of one-week's duration for orthopedists, pediatricians, neurologists and public health physicians, in groups of fifteen.

There will also be courses of instruction of one week's duration for nurses in key teaching positions in

the nursing aspects of the Kenny technique. These will be given for groups of twenty-five.

Courses of two to six months' duration will be offered registered physiotherapy technicians. A series of proficiency tests will be given at the end of a two months' probation period and thereafter until the method is mastered. Upon successful completion of the course, a certificate of proficiency will be issued.

This series of courses will be repeated whenever the occasion demands during the next six to twelve months or until all who desire instruction have received it.

For further information, apply to the director of the Center for Continuation Study, University of Minnesota, Minneapolis.

* * *

Retiring after thirty-nine years of active practice in North Saint Paul, Dr. E. W. Cowern has gone to Seattle, Washington, to make his home with his daughter.

Dr. Cowern, who is seventy-one years old, graduated with honors from Dartmouth Medical College in 1902. He began his practice in North Saint Paul the following year. During the First World War, Dr. Cowern served as medical instructor and later as Camp Sanitary Officer.

Dr. Cowern has served as North Saint Paul health officer, deputy coroner, school physician. He was on the staff of St. John's Hospital for many years, and served as chief of staff for a term.

Four continuation courses were offered at the University of Minnesota Center for Continuation Study last month.

Guest speakers for the course in Otolaryngology, March 2-7, included: Dr. Gordon F. Harkness of Davenport, Iowa, chairman of the section on Laryngology, Otology and Rhinology, American Medical Association; Dr. James H. Maxwell of Ann Arbor, Michigan, assistant professor of otolaryngology, University of Michigan Medical School; Dr. Wellwood Nesbit, professor of otolaryngology, University of Wisconsin Medical School, Madison; Dr. Lyman G. Richards of Boston, director of the Bronchoesophagoscopy Clinic, Massachusetts Eye and Ear Infirmary; Dr. Oliver E. Van Alyea, associate in otolaryngology at the University of Illinois College of Medicine, Chicago.

A course in Diseases of Rectum and Colon was offered March 23-28.

Dr. Mary Karp of Chicago was guest speaker at the continuation course in Anesthesiology for Nurse Anesthetists, March 26, 27, 28. Dr. Karp is clinical assistant in surgery at Northwestern University Medical School and chief anesthetist at Wesley Memorial Hospital.

Guest speakers for the course in Roentgenology of the Head and Neck, March 30-April 1, were Dr. William E. Chamberlain, professor of radiology, Temple University School of Medicine, Philadelphia, and Dr. Arthur E. Childe, roentgenologist, Montreal Neurological Institute, Department of Neurology and Neurosurgery, McGill University, Montreal.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

SURGERY OF THE AMBULATORY PATIENT. L. Kraeer Ferguson, A.B., M.D., F.A.C.S. Lieutenant Commander, Medical Corps, United States Naval Reserve; Assistant Professor of Surgery, University of Pennsylvania; Assistant Surgeon, Hospital of the University of Pennsylvania; Surgeon, Philadelphia General Hospital and Doctors Hospital, etc., etc. With a section on Fractures by Louis Kaplan, A.B., M.D., F.A.C.S. Associate in Surgery, University of Pennsylvania; Associate in Surgery, Mt. Sinai Hospital; in Charge of Fracture Division of the Surgical Out-Patient Department, Hospital of the University of Pennsylvania. 923 pages. Illus. Price, \$10.00, cloth. Philadelphia: J. B. Lippincott Co., 1942.

COMMUNICABLE DISEASE NURSING. Theresa I. Lynch, R.B., Ed.D. Instructor in Education, New York University; Formerly Superintendent of Nurses and Director of Instruction, the Willard Parker Hospital, New York. 678 pages. Illus. Price, \$3.75, cloth. St. Louis: C. V. Mosby Co., 1942.

SYMPTOM DIAGNOSIS. Regional and General. 4th ed. Wallace Mason Yater, A.B., M.D., M.S. (in Med.), F.A.C.P. 900 pages. Price \$10.00 New York: D. Appleton-Century Company, Inc., 1942.

This volume is a valuable supplement to the practicing physician's library as it makes available in convenient form symptoms referable to the various system diseases. To facilitate quick reference there is a complete index and classification under regional symptoms as well as tables of differential diagnosis. This volume should aid in interpretation of symptoms not commonly encountered.

C. A. MCKINLAY.

BORN THAT WAY, Earl R. Carlson, M.D. 174 pages. Price \$1.75. New York: John Day Co., 1941.

This is the autobiography of a victim of spastic paralysis; Dr. Carlson, with marked candor, tells the story of his life. In the first chapter he tells of his childhood, the difficulties he had in learning to walk and talk, how he was taken by his mother from one clinic to another and of their hopeless prognosis. He then tells of the difficulties he had in school, how he was unable to write or recite in his class because he could not control his muscles. He also tells of his many embarrassments during his college course and how discouraged he became during his medical course at Yale, especially in anatomic dissections. The last few chapters are devoted to his experiences in the neurologic clinic for spastics. He describes how muscle training and education have changed children who were once considered hopeless cripples into happy and self-supporting individuals.

I consider this book of great benefit to both the physician and the parents of a spastic child, and I have advised any parents who have one of these children

to get the book and read it, as I am sure they will get a great deal of help and encouragement from Dr. Carlson's own life and experiences.

ALEXANDER STEWART, M.D.

THE CARE OF THE AGED (GERIATRICS). Malford W. Thewlis, M.D. 3d edition. 579 pages illus. \$6.00. St. Louis; C. V. Mosby Co., 1941.

In interesting reading and in condensed form, the author covers our present knowledge of old age. The opening chapter states that Hippocrates, Celsus, Galen, Sanctorious, Kaan Boerhaave, Cicero, and others were familiar with the problems characteristic to the senescent age. Under the chapter "Value of Old Age," there is a long list of names of notable men and women who did their best work between the ages of seventy and ninety years. Among them were Goethe, Herbert Spencer, Oliver Wendell Holmes, Gladstone, the Drs. Blackwell (sisters), Thomas Edison, Mrs. Osler (William Osler's mother), and Rockefeller.

The remaining chapters deal with the neglect of old age, and the various diseases, with treatment, peculiar to the senescent age, and how they differ from pre-senescent diseases. Case histories are freely given. In pneumonia great stress is placed on clinical signs. When there is a normal pulse and an absence of sputum, chill, fever and pain, the frequent white blood cell counts determining the percentage of leukocytes and

BOOK REVIEWS

the presence of toxic granules, which is one of the most constant findings, decides the diagnosis. Roentgen therapy, the author says, has cured some carcinomata, and caused many. He recommends x-ray in diagnosis. In contrast to the normal senescence, is the opposite, where previous sickness, injuries and hardships result in various stages of senescent invalidism.

Old age hasn't definite limiting lines; it can begin in the forties. It covers a large part of one's lifetime. The author shows that it is a valuable age; that it has been a neglected age; and that it is worthy of a place among the specialties.

NELLIE N. BARNES, M.D.

CANCER OF THE FACE AND MOUTH. Diagnosis, Treatment, Surgical Repair. Vilray P. Blair, M.D., Sherwood, Moore, M.D., and Louis T. Byars, M.D. 599 pages. Illus. Price \$10.00. St. Louis: C. V. Mosby Company, 1941.

This last work on carcinoma of the face is probably the most extensive and profound that has yet come out on this subject in the English language. The matter is taken up in systematic form—the cheeks, the neck, the mouth, et cetera, and each handled in a very thorough and detailed manner.

The methods of therapy are well considered including both radiation and surgery, and by far the most valuable part, in my opinion, is the description of the plastic procedures employed by the author and the astonishing results that were obtained in a good many cases as shown by the photographs especially. One must con-

sider how thoroughly hopeless such cases usually are without the plastic procedure. The photographs number well over two hundred, and as it is well known that one picture is better than ten thousand words, one can readily see the extensive value of this work.

At the end of the book there is a chapter dealing entirely with technique on plastic surgery, and this to the surgeon is of paramount value. All in all, this book is a very valuable addition to the works already in existence on malignancy of the face, and it should serve as a criterion to both radiologist and surgeon for a decade of years.

E. Z. SHAPIRO, M.D.

The Japanese death rate is 17.4 per 1,000 as compared to 10 or 11 in the United States. Japan's present death rate, in fact, resembles ours of 1900. Individual causes of death in Japan are about as prevalent now as in this country about 1900. For example, the United States tuberculosis death rate now is 45 per 100,000. In Japan in 1937 the rate was 204, closely resembling our tuberculosis death rate in 1900 of 196. The picture is similar for diarrhea and enteritis. America has more than twice as many men to draw on in the military age group as Japan—25 million men from 20 to 34, as against Japan's 11 million in this age group.—Science News-Letter, Jan. 17, 1942.

CLASSIFIED ADVERTISING

FOR SALE—Lucrative practice, Southwestern Minnesota. Population 2400. New \$40,000 addition to municipally owned, modern hospital. Complete line of surgical instruments. 100 ma. x-ray, fluoroscope. Excellent library, laboratory. Modern well furnished office suite. Benedict-Roth basal metabolism machine. Fisher diathermia. Ferec-Rand refractoscope. Ophthalmometer. Phoropter Bi-chrom check. Streak retinoscope. Overhead low for such a setup. Liquidating preparatory to military service. Address D-10, care MINNESOTA MEDICINE.

FOR NERVOUS DISORDERS

Operated In Connection

with

Homewood Hospital

Plymouth at Penn Avenue, Minneapolis

New and modern in architecture and construction. Six departments affording proper classification of patients. Rooms attractively furnished. Parlor and day room in each department. Buildings located on top of a ridge of hills alongside of Glenwood Park, overlooking the city, surrounded by parks, lakes and woodlands. Ample provision for diversion and helpful occupation. Adequate night and day nursing service maintained. Physicians may direct the treatment of their own patients.

A nonprofit organization open to the medical profession.

Don't Wait Too Long

Illustrated, a handy model for your desk. Approximately 8 inches in diameter and 9 inches high.

It's time to think of hot weather and fans once more. This year try one of the modern KISCO CIRCULAIR units, and you'll be glad your old fan is worn out.

These clever fans lift the cooler air up and distribute it in all directions at one time.

And don't wait too long—as you know—deliveries are pretty irregular these days.

THE REAL IMPORTANCE IN CIGARETTE

Less nicotine in the smoke of SLOWER-BURNING CAMELS

than in that of the 4 other largest-selling brands tested—less than any of them—according to independent scientific tests *of the smoke itself!*

*—when you are advising
patients on the brand
of cigarette to smoke*

MAJOR scientific opinion agrees on 3 facts about cigarette smoking—

1. Nicotine is the chief component of pharmacologic and physiologic significance in cigarette smoke.
2. Nicotine is important to the smoker *only in the smoke.*
3. Available medical research* indicates, and Camel's scientific tests on hundreds of samples show (see pictures), that a slower-burning cigarette produces less nicotine in the smoke.

Then here is the important question:

CAMEL

THE CIGARETTE OF COSTLIER TOBACCOS

OF LESS NICOTINE SMOKE

Is a reduction of nicotine *in the smoke itself* of real physiologic importance to a regular Camel smoker?

A prominent physician states in an important article** on smoking, that when injections of nicotine were increased by only 25%, profound changes in blood pressure occurred.

The "Pleasure Factor"

In addition to a desirable reduction in nicotine intake, Camel offers another big advantage—a bid for patients' cooperation in a program of smoking modification. Camel is the slower-burning cigarette for more mildness, coolness, flavor!

In the same tests, Camel burned SLOWER than any of the 4 other largest-selling brands tested.

For Better Radiographic Results, With More Savings in Office Space Investigate the G-E Model R-38

YOU will enjoy many extra radiographic benefits for every dollar invested in the sensibly priced G-E Model R-38 X-Ray Unit. It brings you 100-milliamperere, big-apparatus quality and flexibility—in an area you may have thought far too small to accommodate a combination unit.

Because the R-38 fits so snugly into small space and a restricted x-ray budget, it pays important dividends for every square foot of floor space it uses. And you will be cheered by the unit's ability to provide those dividends for a long time to come. For the R-38's built-in durability assures long-run economy.

If you want x-ray's benefits but until now have done without them because a combination unit seems too large both physically and as an in-

vestment, investigate the R-38. Clip, fill in, and mail the coupon today for complete and really free information.

Please send complete information about the compact, rightly priced G-E Model R-38 Combination X-Ray Unit.

Taking the virus for a ride...

TAMING THE VIRUSES is a major feature of the vast research program at Lederle Laboratories. Here you see a Lederle scientist about to take one of the killers for a ride on the high speed, air-driven ultra-centrifuge—a tool that has been of tremendous value in facilitating the study of purified, filterable viruses. Whirling at speeds of 30,000 to 60,000 revolutions per minute, it virtually spins the heavier virus molecules dizzy, forcing them to let go their death grip on the tissue specimen. After the ride is over, the virus can be easily separated.

Thus the elusive viruses, cause of more than three score human and animal diseases, are brought out into the open, where research can watch them under control.

vasoconstrictor
circulatory stimulant

*hemostatic
resuscitant*

THE HORMONE THAT DOCTORS FORGET IS A HORMONE

Reproduced from the 1833 edition of "Anatomy of the Human Body" as drawn by the master artist-anatomist and surgeon, Sir Charles Bell. He depicts the "Scheme of the Arterial System."

Although Adrenalin* was the first hormone to be isolated in pure form, it is seldom used to relieve hormone deficiency. Its many common and important uses based on its characteristic actions—as a vasoconstrictor, circulatory stimulant, and hemostatic—have tended to obscure its endocrine origin.

Injected hypodermically, Adrenalin is one of the best and probably the most widely used of agents for rapid relief from asthmatic paroxysms. Applied locally, it is of value in hemorrhage of accessible mucous membrane areas . . . Adrenalin (Epinephrine U.S.P.) finds favor in the prevention and treatment of allergic reactions due to injection of biologicals or arsenicals.

Adrenalin is the pure, natural, 100% active hormone of the adrenal medulla. Adrenalin is produced solely by Parke, Davis & Company.

When a crisis occurs, use Adrenalin.

Why let a busy mother upset your formula balance?

THE OPTIMAL NUTRITION which your baby feeding prescriptions provide... may be lost through errors in formula preparation.

For even the best-intentioned mothers may make mistakes in measuring. Or leave out important supplements. Or fail to follow instructions completely.

Biolac makes such formula errors all but impossible, because:

1. Formulas are made by simply diluting Biolac with water.
2. Biolac provides completely for *all* the nutritional requirements of early infancy except for vitamin C.
3. No supplementary formula ingredients are necessary.

Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrate of vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and sterilized.

4. The adequate carbohydrate content of Biolac is processed in the milk, is in equilibrium and is sterile.

5. The nutritional completeness of Biolac is guaranteed by strict laboratory control of manufacturing operations and assays of product composition which are recognized in its A.M.A. Council acceptance.

Thus in prescribing Biolac you have these extra assurances that your babies will actually receive in their formulas the optimal nutrition you prescribe.

Biolac nutritional values equal or exceed recognized standards. For complete information, write Borden's Prescription Products Division, 350 Madison Ave., New York, N. Y.

INDIVIDUALLY DESIGNED

Abdominal and Back Supports - Breast Supports

These are the Reasons why we say "Try S-M-A"

- Physicians will find that S-M-A* is not a "compromise formula." It is a complete milk formula for infants deprived of human milk.
- Cows' milk fat is replaced with the unique S-M-A fat for easy digestion and adequate nutrition. It compares physically, chemically and biologically with the fat in human milk.
- The carbohydrates in S-M-A and human milk are identical.
- With the exception of vitamin C, the vitamins essential to normal growth and development (B₁, D, and A) are included in adequate proportion in S-M-A ready to feed.
- Furthermore, iron (so difficult to provide for the bottle-fed infant) is included in S-M-A. When prepared each quart provides 10 mg. iron and ammonium citrate.

* * * * *

Excellent results with hundreds of thousands of infants is reason enough why S-M-A is the choice of a steadily increasing number of physicians.

Try S-M-A. Results tell the true story more aptly than words and pictures.

*S-M-A, a trade mark of S.M.A. Corporation, for its brand of food especially prepared for infant feeding—derived from tuberculin-tested cow's milk, the fat of which is replaced by animal and vegetable fats, including biologically tested cod liver oil; with the addition of milk sugar and potassium

chloride; altogether forming an antirachitic food. When diluted according to directions, it is essentially similar to human milk in percentages of protein, fat, carbohydrate and ash, in chemical constants of the fat and physical properties.

S.M.A. CORPORATION • 8100 McCORMICK BOULEVARD • CHICAGO, ILLINOIS

Women and Defense

As in the last war, American women are proving that they can do immeasurably more than "keep the home fires burning". Their part in the defense industries, in the field of nursing, in the various branches of civilian defense, in buying Defense Bonds, and in generally help-

ing to maintain an unconquerable national morale and unity is truly magnificent. . . . The importance of sensible personal care during these days of strain and tension cannot be overestimated. A fresh, well-groomed appearance adds to our sense of personal fitness and helps to bolster morale. . . . In these days there is no excuse for primping; money should not be wasted on needless luxuries. But we submit that necessary aids to good grooming, carefully selected and used economically, are indispensable. . . . Today, overalls and uniforms add a patriotic and therefore glamorous touch to the renowned loveliness of American women. . . . For Defense Buy United States Savings Bonds.

Is absorbed
NOT TOO RAPIDLY
but **RAPIDLY ENOUGH**

Because the effectiveness of Bismuth Ethylcamphorate (injected intramuscularly) endures a longer time than does that of water solutions of bismuth salts, it makes possible a more convenient (weekly) visit interval for the patient. On the other hand, since it is more rapidly and completely absorbed than are oil suspensions of insoluble bismuth compounds, less material in terms of metallic bismuth is needed to maintain a therapeutic level, and danger of toxicity is minimized.

Sterile Solution Bismuth Ethylcamphorate is the bismuth salt of ethyl camphoric acid dissolved in sweet almond oil. It is available in boxes of six and twenty-five 1 cc. ampoules, and in 30 cc. vials.

Fine Pharmaceuticals Since 1886

IPRAL induces sound restful sleep closely resembling the normal. By dulling the consciousness of physical and mental discomfort it helps the patient rebuild vital resources. Dosage is small . . . absorption and elimination rapid . . . and cumulative effects avoidable by proper dosage regulation.

HOW SUPPLIED

IPRAL CALCIUM (calcium ethylisopropylbarbiturate) in 2-grain tablets and in powder form for use as a sedative and hypnotic. $\frac{3}{4}$ grain tablets for mild sedative effect throughout the day.

IPRAL SODIUM (sodium ethylisopropylbarbiturate) in 4-grain tablets for pre-anesthetic medication.

The art of doing things well

IT MAY TAKE years of experience to find the best way to do a thing. Take the problem of sealing ampoules, for instance. That's a job that can be done very well by hand, but it's slow work when every ampoule must be handled individually. The machine way is best. Production steps up when steel fingers are set to molding the smooth tips of heat-softened glass. Quality is better, too, for ampoules sealed mechanically rarely have charred tips and black floaters to plague the inspectors. Lilly Ampoules provide fine medication in finest glass enclosures.

CHEMOTHERAPY IN EXPERIMENTAL TUBERCULOSIS

WILLIAM H. FELDMAN, D.V.M., M.S.

Rochester, Minnesota

TO BE invited to prepare and deliver the John W. Bell Tuberculosis Lecture is a high honor indeed. While I am grateful for that honor, I am also concerned with the responsibility assumed when I accepted your committee's invitation. The subject suggested for discussion was chemotherapy in experimental tuberculosis. In view of the attention given to the chemotherapeutic attack on such a wide variety of different diseases during the past five years, it is perhaps timely that this form of therapy be reexamined in its relation to tuberculosis.

There has been no more fascinating nor epochal phase of modern medicine than the development and clinical application of new drugs that have conquered infections due to streptococci, meningococci, gonococci and pneumococci. This is only a partial list of the infectious agents that have been shorn of their disease-producing and perhaps life-taking propensities by the relatively new sulfonamide-containing drugs. New compounds are constantly being prepared and the possibilities for future development that may eclipse even the spectacular achievements already witnessed are limited only by the imagination of the research chemist.

Although the use of chemical agents in the treatment of infectious diseases has been practiced ever since the discovery of pathogenic bacteria, until relatively recently there have been only three chemotherapeutic agents that might be considered as specific in the treatment of disease. These were mercury for syphilis, quinine for malaria and ipecac for dysentery. Modern chemotherapy dates from 1909 when Ehrlich's

brilliantly conceived and systematically pursued studies culminated in the discovery of arsphenamine. This is considered by many as the greatest triumph of modern chemotherapy up to the time that Domagk announced that prontosil when given orally had prevented the development of otherwise fatal hemolytic streptococcal infections in mice. Although Domagk's work apparently was done in 1932, it was not announced publicly until February, 1935.⁴

The present successful but limited chemotherapy which has revolutionized the treatment of many bacterial infections has stimulated an interest in this form of therapy that is comparable to that generated by the findings of Lister and those of Ehrlich. Theoretically it should be possible to provide for every bacterial and parasitic disease a suitable chemical substance that will destroy the infective agent without exerting serious toxic effects on the host. However, up to now there exist many practical considerations that impose definite limitations to the general application of chemotherapy. Nevertheless when one considers what has been accomplished during the relatively short period since the therapeutic value of prontosil was discovered, it is difficult to overstate the possibilities of the future.

In this presentation the time allotted makes it necessary that the subject matter be somewhat circumscribed. Successful chemotherapy in tuberculosis has been the objective of countless investigations since the time of Koch. To give a detailed account of all the attempts that have been made to find a chemical substance that would be effective against a tuberculous infection would perhaps be unwarranted, since several excellent

John W. Bell Tuberculosis Lecture, Minneapolis, Minnesota, February 2, 1942. From the Division of Experimental Medicine, The Mayo Foundation, Rochester, Minnesota.

reviews are available for those who are especially interested. Suffice it to say that although the agents tried have included such diverse substances as the heavy metals and the fatty acids of chaulmoogra and of cod liver oil, the long awaited and fervently hoped for chemical agent that can be depended on to combat successfully tuberculosis in human beings, remains to be demonstrated.

Writing in 1923, Calmette concluded his discussion of the chemotherapy of tuberculosis by the following statement: "It must be recognized that up to the present despite the great number of attempts made to discover among chemical agents a substance capable of arresting the development of experimental tuberculosis in the guinea pig and the rabbit, these efforts have been in vain." This conclusion was essentially that of Wells and Long²⁰ who wrote in 1932 that "No specific chemotherapeutic agent has been found for tuberculosis. No chemical yet used has cured the disease in the experimental animals employed." Corper² recently reviewed the question of chemotherapy of tuberculosis. He evaluated the data available up to the early part of 1940 and concluded that there was no specific chemotherapeutic agent of proved value in tuberculosis either in the sense of Ehrlich in which drugs in lethal doses are able to kill all the specific disease-producing organisms within the body at a single dose or in an etiotropic or parasitotropic sense. Kolmer and Tuft, writing in 1941, concluded that the only agents that have been at all effective in the chemotherapy of tuberculosis are the compounds of gold. These were considered, however, too toxic to warrant general use.

From the data that have accumulated concerning the attempts to obtain and demonstrate a chemotherapeutic agent that would combat tuberculous infections successfully, it is evident that the quest has been largely disappointing. Under the circumstances, announcement of results that indicate that a chemotherapeutic substance has been found that is capable in many instances of combating experimental tuberculosis successfully should be viewed with skepticism and the data subjected to a critical analysis. Until the facts in support of apparently favorable results are established firmly by repetition of the original experiment and are confirmed by independent workers, it is wise to maintain a conservative attitude concerning chemical substances said to have thera-

peutic value in tuberculosis. Investigators who are concerned primarily with facts and not fantasies will welcome criticisms and a challenging attitude by those motivated by a sincere interest in distinguishing the true from the false. It is in this spirit that Dr. Hinshaw and I have announced from time to time the results of our work with the chemotherapy of tuberculosis.^{5, 6, 7, 8, 9, 13} We have been cautious about making specific claims, feeling that facts are easier to demonstrate than claims are to defend.

Before discussing the problem of treating tuberculosis by specific chemical substances, it might be profitable to provide a definition of chemotherapy. The term has been used rather loosely by some and apparently has meant different things to different authors. In a general sense treatment of a disease by a drug or chemical is chemotherapy. However, through the years there has been a tendency to limit the term chemotherapy to the specific treatment by drugs which act on the infective agent without seriously affecting the tissues of the host. Kolmer and Tuft defined chemotherapy as "the prevention and treatment of an infectious disease by specific chemical agents without marked or serious toxic effects" on the patient. This is an acceptable modern concept of the term and is more applicable to reality than the original concept of Ehrlich in which chemotherapy meant literally the disinfection of the infected body by a single dose of a specific chemical agent.

Practical Consideration of the Problem

There exist certain practical obstacles that confront the investigator desirous of initiating a comprehensive study of chemotherapy of experimental tuberculosis. There must be available proper physical equipment, adequate funds and intelligent and enthusiastic assistance if a satisfactory program is to be evolved. The project must be undertaken with the knowledge that it cannot be finished in a week, a month or even a year.

Up to the present time we do not know of any short cuts whereby the efficiency of a chemotherapeutic agent intended to combat a tuberculous infection can be determined definitely. It is true that tests *in vitro* can be and sometimes are used to determine the effects of a chemical substance on tubercle bacilli. While this method is not without merit and perhaps capable of a wider application, it is, we feel, inferior to the animal test in

which animals actually affected with tuberculosis are subjected to treatment. While the latter procedure is time-consuming and relatively expensive, it will provide information that can be obtained in no other way. It should be evident that conditions *in vitro* can never be other than artificial and that complicated organic compounds such as constitute most chemotherapeutic agents are likely to act and be acted on quite differently in an artificial medium than when in contact with the natural fluids and tissues of a living organism. In this connection it might be apropos to draw attention to the view that antibacterial substances such as the sulfonamides operate by depriving the bacteria of certain essential accessory food factors or metabolites which have been likened to vitamins and of which para-aminobenzoic acid is one example.

Additional knowledge of the synthesis necessary for bacterial growth may suggest eventually a procedure whereby the worth of a chemotherapeutic agent in tuberculous infection may be determined by tests *in vitro* rather than by procedures *in vivo*. The need for an accurate, simple test that can be completed within a few days at the most and in which the results can be interpreted in terms of the test *in vivo* is apparent to all who are concerned with the problem of chemotherapy as it pertains to tuberculosis.

In most other infections the value of chemotherapy has been determined relatively quickly by the use of the mouse. Biologically, however, this animal is unsuited for work involving human tubercle bacilli. The animal of choice continues to be the guinea pig. The marked susceptibility of guinea pigs to experimentally induced tuberculosis provides a circumstance of considerable importance in testing chemotherapeutic substances. If one is fortunate in establishing a proper balance between the dose and virulence of the bacilli and the susceptibility of the animals to be used it is possible to initiate a slowly and definitely progressive tuberculous disease that is not reversible. At least in our experience we have never encountered what we considered spontaneously resolved or cured tuberculosis in the guinea pig. If an animal of such marked susceptibility as the guinea pig becomes tuberculous as a consequence of experimental procedures and subsequently is apparently freed of the infection as a result of a definite therapeutic agent, the results should be significant.

Tuberculosis, whether naturally acquired or experimentally induced, differs greatly from most infections that have been found to be amenable to a chemotherapeutic attack. In tuberculosis the problem is not that of simple septicemia or an acute inflammatory process but is instead an elaborate pathologic complex consisting of bacteria of considerable tenacity, harbored within the protection of a morbid structure that is frequently extensive and of long standing.

It has been generally believed that successful chemotherapy is especially difficult in tuberculosis because of factors that are characteristic and inherent to the disease. These factors include the alleged impermeability of the morbid structure due to the avascularity of the tuberculous lesion and the high resistance of the protoplasm of the tubercle bacillus to penetration by chemical substances. These features, which have been discussed at some length by Wells and Long¹⁹ and by others, do not provide, in my opinion, an adequate explanation for previous failures to demonstrate in tuberculosis the successful chemotherapy that has been and is being accomplished with certain other infective diseases. Under natural and experimental conditions we know that tuberculous lesions, in spite of their avascularity, are penetrated by substances such as calcium and, as Wells and Hedenburg¹⁸ showed experimentally, by potassium iodide. By the use of intravital dyes it has also been demonstrated that tuberculous lesions are permeable.

The difficulty of the problem is not that of the permeability of the lesion but of providing a substance that, while not unduly toxic to the normal tissues, will be able to reach all parts of the morbid structures in a form that will kill the bacilli by selective bactericidal action, or will have a neutralizing effect on the products of the bacilli or will promote a stimulation of the reticulo-endothelial elements that are concerned with the cellular immunologic mechanism of defense. Should a chemical compound be developed which when given with therapeutic intent to a tuberculous animal achieves a desirable therapeutic effect, the exact mechanism by which the effect actually would be accomplished is likely to be obscure.^{11*} The possibilities for complex biochemical reactions between the substance when it enters the body and the histiocytic and related elements of the tuberculous focus are infinite

*Possibilities as to the manner in which antibacterial substances function have been discussed by Fildes.¹¹

and unpredictable. In considering chemotherapy one should keep in mind that the substance finally operative against the tubercle bacillus or against the morbid process generally is likely to be chemically quite dissimilar to the substance as it was introduced into the body.

Important Factors in the Critical Evaluation of a Chemotherapeutic Agent

From our limited experience in the field of chemotherapy we have become aware of the necessity of recognizing certain factors that we believe are important in the critical evaluation of a chemotherapeutic agent intended to combat experimentally induced tuberculosis. These factors are as follows:

1. *The virulence of the bacteria used to establish the infection.*—This, we believe, is one of the most important factors. Since the virulence of different strains of tubercle bacilli is subject to marked variation and since the virulence of the same strain is likewise unstable or at least unpredictable, an understanding of the factors that control or influence virulence of tubercle bacilli is essential. In most of our work we have preferred to use a strain of tubercle bacilli (H37RV)[†] whose history and biologic characteristics have been established by a prolonged period of observation and by an extensive investigation of its biophysical characteristics.¹⁵ This strain, which we obtained originally from Dr. Arthur J. Vorwald of Saranac Lake, New York, has retained to date the virulence it possessed when it came into our possession in 1940. We have continued its cultivation by subculturing monthly on the synthetic medium of Proskauer and Beck.

A strain of tubercle bacilli of satisfactory virulence is one that when injected into guinea pigs in medium to small doses will produce typical progressive and uniformly fatal experimental tuberculosis. The appearance of inconsistencies in the results in the control animals should invalidate what otherwise might appear as significant results. Incidentally, accumulated experience indicates that in chemotherapy there exists no correlation between the virulence of the parasite and its resistance to chemical agents.

2. *Relation of duration of infection to beginning of therapy.*—Theoretically at least it should

be less difficult to impede the progress of a tuberculous infection if the deterrent agent is present before or very soon after the animals are inoculated with tubercle bacilli than would be true if treatment is delayed until anatomic signs of the disease are definitely present. In other words we should be more concerned with the effect that a chemotherapeutic substance may have on a tuberculous infection already established than with the ability of the substance to exert a prophylactic action. From information obtained from our experimental studies Dr. Hinshaw and I more or less arbitrarily have considered six weeks as the minimal duration that an experimental tuberculous infection must have existed before therapy is started. If guinea pigs are inoculated subcutaneously with relatively small doses of human tubercle bacilli of standard virulence, there will be present in the majority at the end of six weeks small multiple focal lesions of tuberculosis. The lesions will be most common in the spleen and less frequent in the lungs and liver. The lesions at this time are usually actively progressive. Histiocytic and epithelioid cells predominate and necrosis is the exception rather than the rule. We have at this stage of the infection a definite and characteristic disease whose pathologic characteristics are those of a process that is advancing and may be expected to continue its destructive course with spontaneous resolution extremely unlikely.

Since the results of our work with "promin" have indicated that this drug is capable of exerting a favorable deterrent effect on tuberculous infections established in guinea pigs six weeks before treatment begins, we have adhered to this practice in all subsequent studies. It has been demonstrated repeatedly in our work that we possess in "promin" a drug capable of influencing favorably a tuberculous infection in guinea pigs that had existed six weeks before treatment was started. Therefore it seems reasonable to insist that in the future untried drugs be subjected to the same experimental condition. It appears that unless a chemotherapeutic substance can act effectively against an experimental tuberculous process that is morphologically recognizable when therapy is started the possibilities for the clinical use of such a drug are unimpressive.

3. *Evidence that each animal to be treated was actually and unquestionably harboring a tu-*

[†]A detailed account of the biologic characters of H37RV will be found in the report by Oatway and Steenken.¹⁵

berculous infection before treatment began.—This can be determined by: (1) the tuberculin test; and (2) histologic or other examination of tissue obtained at biopsy, six weeks after inoculation with tubercle bacilli.

4. *Evidence of beneficial effects as a consequence of the therapeutic agent.*—The treated animals as a group should live longer than those not treated, but of more importance than the survival time will be the influence, if any, that the drug has had in altering the expected dissemination of the disease, the amount and severity of the morbid process and the histologic character of the cellular elements constituting the tuberculous reaction.

5. *Permanence of therapeutic effect.*—It should be recognized that the therapeutic effect of a drug may be relative rather than absolute. The drug may act as a bacteriostatic agent preventing the multiplication of the bacteria but without the ability to kill the organisms. Again the compound may exert what Corper, Cohn and Bower³ designated as "organic toxic" or "leukotoxic" effects in which there is a suppression by the drug of the parent cells which give rise to the monuclear histiocytic forms that constitute the cellular response to infection with tubercle bacilli. This would result, according to Corper, Cohn and Bower, in an apparent rather than a real retardation of the tuberculous infection. Although tubercles may not form, the tubercle bacilli remain viable and capable of subsequent mischief.

When the therapeutic agent is withheld until the disease has become sufficiently well established to enable tubercles to form, we have present a hyperplastic rather than an aplastic structure. If such lesions regress or eventually disappear during chemotherapy, it seems probable that the drug has had a direct effect on the infection.

To establish definitely that the favorable effect on an experimental tuberculous disease is permanent rather than temporary is not an easy task. The problem may be approached by: (1) culturing for tubercle bacilli or by inoculating into other guinea pigs, material prepared from the principal organs of predilection from animals that have been treated and are without recognizable tuberculous lesions at the time of necropsy; or (2) treatment of animals that have been receiving a given compound for a long period may

be discontinued and the animals continued under observation indefinitely to determine if a residual infection that was latent when treatment was stopped will become manifest as a progressive and fatal disease. This latter procedure conceivably could give rise to false conclusions. Unless the animals are placed in a nontuberculous environment when chemotherapy is stopped, it may be difficult to determine with certainty that lesions of tuberculosis that may be observed months later at necropsy are not the result of an exogenous reinfection rather than the manifestation of an endogenous infection that successfully resisted the action of the therapeutic agent.

6. *Recognition of the possibility that different strains of tubercle bacilli may reveal important variations in their resistance or susceptibility to chemotherapeutic agents.*—Since chemotherapy in tuberculosis has been for the most part unsatisfactory and unpromising, precise information regarding the resistance or susceptibility to chemical substances of a representative number of different strains of tubercle bacilli is not available. Even though a compound is found that is effective in combating experimental tuberculosis induced by a specific strain of the tubercle bacillus, it would be injudicious to claim that the drug would be equally effective against all strains of the organism.

7. *Confirmation of results by others.*—If the results are to be accepted with confidence, it is important that the original observations be confirmed by independent workers. Many factors enter here to make this condition frequently difficult of achievement. If one undertakes to confirm another's work, it seems important that the original experiment be duplicated in all essential details. If the original procedure is not followed, the deviation should be stated. While acceptance of these basic principles in theory is practically universal, rare indeed is the instance in which a critical confirmatory experiment is carried out by duplicating every detail of the original work. If the results confirm the original observations, the procedure followed is perhaps of secondary importance, but if the results are contrary to those of the original study, it is not proper to claim that the original data could not be confirmed unless the original experiment was actually duplicated.

Original Observations

Our interest in chemotherapy of experimental tuberculosis had its beginning about the time the report of the work of Reid and Follis with sulfanilamide was published. Dr. Hinshaw had obtained for clinical investigation a quantity of sulfapyridine which he was using in the treatment of pneumonia. The fact that this drug appeared to have a wider antibacterial activity than was originally supposed suggested to us the desirability of testing it against an experimental tuberculous infection.

Incidentally, the importance of the work of Reid and Follis with sulfanilamide should, I believe, be emphasized. While they were properly conservative in their conclusions, the fact remains that their experiment showed that the development of tuberculosis in the guinea pig is definitely inhibited by sulfanilamide. Their data indicated clearly that an adequate dosage of the drug is an essential factor in the results obtained and that unsatisfactory or negative results will follow the use of an inadequate dosage. After the published announcement of Reid and Follis' work a number of reports were published by workers who attempted to confirm Reid and Follis' observations. While a few obtained results quite comparable to those of Reid and Follis, several did not and it is well to note that those who failed to confirm the original results failed to observe certain important factors that were clearly apparent in the report of Reid and Follis. These factors were adequate dosage and administration at intervals throughout the day to maintain an effective concentration in the blood and continuation of the treatment for the duration of the experiment.

Dr. Hinshaw and I believe that the work of Reid and Follis is of considerable importance because of the soundness of their experimental method and because their results indicated that tuberculosis even in the highly susceptible guinea pig could be inhibited in its expected course by a chemotherapeutic agent.* Their results provided reasons for believing that tuberculosis, one of the most drug-resistant of all infectious diseases, may yield eventually to a specific chemical substance. We still believe this is possible of achievement.

During the three or more years that we have been exploring the possibilities of chemotherapy as a means of combating experimental tuberculous infections, we have assembled sufficient data on nine different compounds to indicate which are of no value and which merit further investigation. The total number of compounds studied is not large and is only mentioned to emphasize the amount of time and energy necessary actually to test substances that theoretically may appear promising.

The different experiments which have been completed to date will now be described briefly.

Study 1.—Our first study was concerned with sulfapyridine. Two groups of guinea pigs, each consisting of twenty animals, were used. All the guinea pigs received subcutaneously over the sternum 0.0001 mg. of a recently isolated strain of tubercle bacilli, human type. For three days prior to inoculation with tubercle bacilli and for seven days after inoculation each of the animals in group 1 received twice daily by mouth 250 mg. of sulfapyridine.* After ten days the dose of sulfapyridine was reduced to 125 mg. given twice daily. Group 2 received tubercle bacilli only. After twenty-one days, when a guinea pig in one group died, an animal in the other group was killed for the purpose of comparison. The experiment was continued for fifty-six days after the injection of tubercle bacilli, when the animals that were living were killed for necropsy.

Twelve of the animals that received sulfapyridine lived three weeks or more. In the control group, four animals died during the last five weeks of the experiment; seven were killed during the same period for comparison with seven animals receiving sulfapyridine that died during this period. Nine were killed when the experiment was terminated. Subsequent studies revealed that tuberculosis had become definitely established in one or more situations in all the treated guinea pigs that lived longer than twenty-one days. Furthermore, the general situation indicated that these animals might have been expected to die eventually of the disease had the experiment been continued indefinitely. However, appreciable differences did exist in the character of the disease in the two groups of animals. These differences, it seems reasonable to pre-

*In a later report Follis and Reid presented evidence indicating that in tuberculous rabbits sulfanilamide in adequate dosage, properly administered, has a definite inhibitory effect on the development of the disease.

*The sulfapyridine was kindly supplied by Dr. D. F. Robertson, Associate Medical Director, Merck and Company, Rahway, New Jersey.

sume, were due to the effect of sulfapyridine. For reasons that appear to be inexplicable, the differences in the character of the lesions were most striking in the axillary lymph nodes contiguous to the site where the tubercle bacilli had been introduced and in the spleen. In those animals that did not receive sulfapyridine, the amount and character of the tuberculous changes in these tissues were severe and well marked, with caseation a prominent feature. By all criteria, there was present a progressive, destructive tuberculous infection that was unaccompanied by recognizable evidence of restraint.

These changes were in sharp contrast to the pathologic picture in the spleens and axillary lymph nodes of the animals that received sulfapyridine. With few exceptions there was present in such animals impressive and significant evidence that some inhibitory mechanism had been operative, with measurable success. The failure of the infection to be demonstrably present in the axillary lymph nodes of all but two of the treated animals seems important, as does the character of the disease in the spleens of all but one of the animals that received the drug. The failure of all the spleens but one to become hyperplastic is certainly contrary to what happened in the spleens of the animals that were not treated. Microscopically the lesions in most of the spleens from the treated animals were definitely those of tuberculosis that was unlike that in the controls. The tubercles were usually discrete epithelioid structures with necrosis absent or of minimal proportions. The tendency of the tubercles to remain for the most part within the confines of the splenic corpuscles is a significant feature that did not occur in the spleens from the untreated animals. Generally speaking, the inhibitory effects we observed were comparable to those produced with sulfanilamide as reported by Rich and Follis.

From the data obtained in this study we concluded as follows:

1. Sulfapyridine exerted a definite modification and retardation of the expected course and character of the disease in the animals receiving the drug.
2. The effects of the drug were most noticeable in the character and extent of the disease in the spleen and axillary lymph nodes.
3. Although certain desirable modifications in the character of the tuberculosis occurred in

most of the guinea pigs that were treated, the results did not imply that sulfapyridine would be of value in the clinical treatment of tuberculosis.

Soon after we had completed our work with sulfapyridine, two additional compounds intended primarily for use in the treatment of a variety of nonmycobacterial diseases became available for investigational purposes. One of these was sulfathiazole and the other was designated by the manufacturer as "promin."

Our experience in administering to guinea pigs sulfapyridine orally twice daily for approximately eight weeks was sufficient to emphasize how laborious and time-consuming this procedure could be. Consequently, when the manner in which sulfathiazole and promin were to be given was considered, two other methods were tried. The instructions from the manufacturer were that promin should be given parenterally and this we tried to do. However, it soon became apparent that the parenteral administration of promin to guinea pigs was not satisfactory. We next tried giving the drugs mixed with the feed. This method proved convenient and satisfactory for both drugs. It not only presents a minimum of difficulties but has the important virtue of providing a more or less continuous intake of the drug during each twenty-four hours.*

Study 2.—The chemotherapeutic efficacy of sulfathiazole for experimental tuberculosis was determined by mixing 1 per cent by weight of the drug in the feed of thirty guinea pigs. Two days after administration of the drug was started, the thirty animals just mentioned and twenty controls were inoculated subcutaneously with 0.0005 mg. of the virulent variant of H37 designated by Oatway and Steenken as H37RV. All the untreated controls were dead eighty-two days after the experiment began. During this period twenty-one, or 70 per cent, of the treated animals also had died. Four additional animals in the treated group died during the next three days. The five remaining guinea pigs in the group that were receiving sulfathiazole continued to receive the drug daily until the experiment was terminated 164 days after inoculation.

This was not an entirely satisfactory experiment owing to the fact that many of the animals

*Incidentally it appears that promin is far more effective against an experimental tuberculous infection when given orally than when given parenterally.

in the treated as well as in the untreated group died as a consequence of a severe nutritional disturbance. The findings at necropsy indicated that there was little if any difference in the amount

diaminodiphenylsulfone-N,N'-didextrose sulfonate. From the structural formula shown in Figure 1 the relationship of this drug to 4,4'-diaminodiphenylsulfone is apparent. Although 4,4'-diaminodiphenylsulfone is a highly effective chemotherapeutic agent, its marked toxicity has limited its clinical application. In promin the addition of the glucose radicals and of the sodium sulfonate groupings increases the solubility of the drug and presumably decreases its toxicity and perhaps its therapeutic efficacy.

Our first experiment to determine the effect of this compound on tuberculosis experimentally induced can be described briefly as follows: Fifty adult male guinea pigs were divided into two groups. One group consisted of thirty animals; these were to receive promin mixed with the feed to the amount of 1 per cent of weight.* The remaining twenty animals constituted the untreated or control group. After the thirty animals in the first group had been receiving the drug for two days, all the animals in this group and each of the twenty guinea pigs in the second group were inoculated subcutaneously with 0.0005 mg. of a recently prepared subculture of H37RV. The animals in the treated group continued to receive promin in their diet daily for eighty-two days or until all the animals in the control group had died.

As mentioned before, study 2 and study 3 were made concurrently. Consequently the same inadvertent nutritional disturbance that complicated the interpretation of the results with sulfathiazole was also operative in the animals that received promin. Yet in spite of what appeared to be premature deaths among the animals in the treated as well as in the control groups, the results indicated quite clearly that promin had had a deterrent effect on the expected course of the disease. When the last of the controls died eighty-two days after being inoculated with tubercle bacilli, 83 per cent of the animals that had received promin were living. At this time promin was removed from the diet of twelve of the twenty-four survivors while administration of the drug was continued in the diet of the remaining twelve. The experiment was terminated eighty-two days later at which time thirteen animals were living, eight of which had not received promin during the last eighty-two days of life.

Sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate ("promin")

Fig. 1. Structural formula of sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate ("promin").

and character of tuberculosis in the animals constituting the two groups. Although the nutritional disturbance was the immediate cause of death of many animals in both groups, it also happened that many other animals in both groups died as a consequence of their tuberculosis. The fact that five of the treated animals were living and continuing to receive the drug for eighty-two days after the controls had died perhaps suggests that the treatment had the effect of delaying in these animals what inevitably would have been death from tuberculosis. Each of the five animals was moderately to severely tuberculous after having received sulfathiazole for a total of 164 days. The results of this experiment indicated quite definitely that any effect this compound may have had on the course of the tuberculous infection was insignificant and that further trial of the drug in the chemotherapy of tuberculosis would be unwarranted.

Study 3.—Study 2 and study 3 were conducted concurrently. We were thus able to utilize the same group of controls for both experiments. This practice, which we have followed in subsequent work, not only effects an economy when more than one chemotherapeutic substance is to be tested; it also provides a common control factor that is important when comparative studies are being made.

Promin, which Dr. Hinshaw had been using with fairly satisfactory results in treating pneumonia, is known chemically as sodium p,p'-

*The promin we have utilized in our experimental studies was supplied through the courtesy of Dr. E. A. Sharp, Parke, Davis and Company, Detroit, Michigan.

Although lesions of progressive tuberculosis were present in the organs of predilection of all the animals of the control group, the degree of tuberculous involvement in the animals that received promin was notably less than in the control group. Fewer situations were affected and the lesions were fewer and smaller than was true in the guinea pigs that were untreated. Furthermore, in the spleen, liver and lungs of approximately 52 per cent of the treated animals cellular reactions that could be considered tuberculous were not found either grossly or microscopically.

During the course of this experiment an effort was made to determine whether or not spleens which appeared not to contain any lesions were actually free of virulent tubercle bacilli. Each of seventeen spleens of animals that had been treated with promin was divided and a portion emulsified for inoculation into two additional guinea pigs. Of the seventeen spleens, nine were found to contain viable tubercle bacilli and eight did not. Viable tubercle bacilli were demonstrated in all but one of the five spleens in which lesions of tuberculosis were present and positive results were obtained from five spleens in which lesions of the disease were not found. Lesions of tuberculosis were found in the spleen of only one of the five guinea pigs that had received promin for the entire period of observation—164 days—and three of the five spleens in which lesions were found were from animals that had received the drug for eighty-two days only. These observations make it evident that tubercle bacilli may persist in the apparently nontuberculous splenic tissues of animals that have received promin for as long as 164 days and be capable of inducing lesions of tuberculosis in untreated guinea pigs although the bacilli presumably were unable to do so in animals receiving promin. That many of the spleens were free of virulent tubercle bacilli, presumably as a consequence of the promin, was likewise established. It is also evident that tubercle bacilli may remain latent in tissues of guinea pigs long after treatment has been discontinued. This suggests the possibility that immunity developed in these animals, since subinoculation proved the virulence of the dormant organisms.

The information obtained in this experiment provided sufficient reasons for concluding that promin under the conditions imposed had a measurable chemotherapeutic effect on a tubercu-

lous infection induced in a highly susceptible animal with a strain of human tubercle bacilli of known virulence. The longer survival time of the treated animals, the lesser amount of actual disease present and the nonprogressive nature of the lesions in the animals that received promin constitute reasonably convincing evidence in support of the foregoing conclusions.

Study 4.—The results obtained in study 3 indicated that in the treatment of experimental tuberculosis promin had therapeutic properties greatly in excess of any other compound with which we were familiar. That our observations with this substance should be extended was of course obvious. Consequently another experiment was undertaken. It had as its objectives the following: (1) to confirm if possible the observation that, when administration of promin is begun shortly before inoculation with tubercle bacilli, the drug will retard and in some instances prevent the development of tuberculosis; (2) to determine if promin might have a therapeutic effect on a tuberculous infection definitely established before treatment with promin was begun.

In study 4 the infective agent, the diet, and the dosage and administration of promin were the same as obtained in study 3. Eighty guinea pigs were used. Twelve did not receive promin and forty-eight of the remaining animals were divided into six groups of eight animals each. In these six groups administration of promin in relation to the time of infection was as follows: day of infection, three days after, one week after, two weeks after, four weeks after and six weeks after. In twenty animals the administration of promin was started, as in study 3, two days before the animals were injected with tubercle bacilli. At the expiration of six months all the untreated animals were dead, presumably as a result of the severe and widely disseminated tuberculous infection, while only eleven, or 16 per cent, of the treated animals had died during this period. Fifty-seven, or 84 per cent, of the treated animals survived. Among the sixty-eight animals that had received promin, demonstrable lesions of tuberculosis were absent in the liver, spleen and lungs of thirty-nine, or 57 per cent, while no lesions were found in the visceral organs of predilection, at the site of injection or in the contiguous lymph nodes in twenty-nine, or 43 per cent, of the treated animals. In view of the

longer survival time of the treated animals and the fact that the animals that received promin had less demonstrable tuberculous disease and that the disease was usually static or regressive, it was concluded that under the conditions of the experiments described in studies 3 and 4, promin had a deterrent effect on an experimental tuberculous infection.*

Study 5.—The tendency of promin to produce hemolytic anemia is one of the important factors that must be reckoned with in its clinical application. Although promin is fairly well tolerated by guinea pigs even after prolonged and continuous administration, it was recognized early in our work that this drug, like most other chemotherapeutic substances, is a poison and as such is potentially dangerous. The severity of the hematologic changes in guinea pigs produced by promin is generally speaking less than may be expected in adult human beings. Fortunately the changes in the blood induced by promin have not been irreversible in our experience. When administration of the drug is stopped, the hemopoietic response is soon adequate for normal physiologic demands.

To reduce or perhaps avoid the undesirable blood changes that are likely to occur, especially in human beings subjected to prolonged and more or less continuous therapy with promin, intermittent administration of the drug was suggested. To provide information regarding the relative efficacy of promin given intermittently to combat a tuberculous infection the following animal experiment was carried out. The animals consisted of fifty-one guinea pigs, all of which were inoculated subcutaneously with 0.0005 mg. of a recent subculture of the virulent variant of H37 (H37RV). At the end of forty-two days all the animals were found to be sensitized to tuberculin, injected intracutaneously. The fifty-one animals were divided at this time into two groups, one group consisting of twenty animals that were to receive treatment with promin intermittently and the other group of thirty-one animals that were to remain untreated for control purposes. The schedule of treatment for the animals in the first group provided that the drug should be given for seven days every alternate week. In other words, a week of treatment

was to be followed by a week during which no drug was given. As in previous experiments, the drug was incorporated with the feed to the amount of 1 per cent by weight. The experiment continued until all the animals in the control group were dead. This occurred 224 days after the animals had been inoculated with tubercle bacilli. Five days later the surviving animals that had been receiving promin every alternate week were killed.

When the experiment was terminated 229 days after the animals had been inoculated with tubercle bacilli, the thirty-one guinea pigs in the untreated group were all dead while twelve, or 60 per cent, of the animals that had been treated were still living. Of the eight guinea pigs in the treated group that had died, two had received promin for one week only and they died as a consequence of severe and extensive tuberculosis. The longest any of the treated animals that died had received promin was fifty-five days. Those that survived and were killed after 229 days had received a total of ninety-four days of treatment. This represents approximately thirteen alternate weeks.

That the administration of promin had influenced the morbid expectancy of the animals in the treated group markedly was clearly apparent when a comparison was made of the amount of tuberculosis in the treated and in the untreated groups. This difference could be expressed numerically when the amount and character of tuberculosis found microscopically in each animal were determined.* The average numerical index of infection for the thirty-one animals in the control group was found to be 8.7 while the average for the twenty animals that received promin every alternate week was 3.8. In another experiment (study 6) in which the infected animals received promin daily starting with the forty-second day after inoculation with tubercle bacilli, the average numerical index of infection was 2.5. Thus it becomes evident that in combating experimental tuberculous infections in the guinea pig, promin given daily continuously has a greater efficacy than when given daily every alternate week. Whether or not the toxicity

*The scheme we follow for determining the numerical index of tuberculous infection in guinea pigs is based on the arbitrary acceptance of the figure 10 as representing the maximal severity of the disease possible for a given animal. Tuberculosis of the spleen, lungs and liver respectively is graded 1 to 3 depending on whether the character of the disease is minimal, moderate or severe. If lesions are present in the region of inoculation even though lymph nodes may or may not be involved, the index of infection for this region is considered as 1.

*A detailed account of the procedures followed and of the results obtained in studies 3 and 4 will be found in the paper by Feldman, Hinshaw and Moses.⁹

of the drug for guinea pigs was less by the intermittent than by the continuous method of treatment we are unable to say, since no studies directed toward this feature of the experiment were carried out.

In this experiment it might be well to recall (1) that forty-two days had elapsed after the animals to be treated had been inoculated with tubercle bacilli, (2) that two of the animals died of extensive tuberculosis after receiving treatment for only seven days (this is indicative of the virulence of the infection) and (3) that the drug was given, not continuously but intermittently, with seven-day intervals between courses of treatment. That promin was capable, under these conditions, of exerting a therapeutic effect seems worthy of special emphasis.

Study 6.—The evidence we had obtained from the previously described experiments indicated that (1) promin was capable of extending the survival time of the animals that were treated; (2) when treatment was started before or soon after the infection was introduced, the drug in many instances seemed to prevent the establishment of morbid changes characteristic of an experimental tuberculous infection, and (3) in instances in which the infective agent was introduced as long as six weeks before treatment was started, the anatomic character of the disease was altered markedly or recognizable signs of the disease were missing when the animals were examined at necropsy. The evidence that led to these conclusions was based largely on a comparison of the results obtained in the treated animals with the results obtained with the untreated controls. In order that more impressive morphologic evidence might be assembled which would provide reasonable proof as to whether or not a deterrent effect had been exerted on a tuberculous process that was demonstrably present before treatment began, the following experiment was done.

A total of fifty-one guinea pigs was inoculated subcutaneously with tubercle bacilli, strain H37-RV. At the forty-second day when all were found to be sensitized to tuberculin intradermally administered, the animals were divided into two groups. Group 1 consisted of thirty-one animals. These were not treated and were con-

sidered as controls.* Group 2 consisted of twenty animals and starting with the forty-second day each animal in this group received daily with its feed approximately 300 mg. of promin. One week later laparotomy was performed on all the animals in group 2 and on twelve animals in group 1.† This was for the purpose of obtaining for microscopic study specimens for biopsy of the livers of the respective animals. Five animals died as a consequence of laparotomy, one in the control group and four in the group that was being treated.

As a consequence of the observations at biopsy it was determined definitely that tuberculosis was present in the livers of both treated and untreated animals at the time treatment was begun. These findings were compared eventually with the findings obtained from a study of the tissues secured at necropsy. The experiment continued until the last of the animals in the control group had died. This occurred 224 days after infection. At that time only three, or 19 per cent, of the treated animals that had survived laparotomy were dead.

The results of this study quite definitely confirm our previous observations that promin is capable of exerting a definite therapeutic influence on previously established experimental tuberculosis. The procedure followed provided morphologic evidence that in most instances tuberculous lesions present when treatment began resolved or became atrophic or regressive under the influence of the therapeutic agent.

This study strengthens rather than weakens confidence in the ordinary control methods of animal experimentation. The data obtained are entirely consistent with those secured in other experiments in which biopsies were not done. However, the procedure followed in this study makes it possible to know with certainty that lesions of tuberculosis were actually present during at least the early phases of the treatment. How much time was required for lesions to resolve in those animals that were without recognizable lesions when the animals were killed after receiving treatment for 184 days is not known.

The difference in the mortality rate and in the amount and character of the tuberculous disease present in the two groups of animals indicates

*This experiment was conducted concurrently with study 5. Consequently the same group of controls sufficed for this and certain other experiments.

†The surgical procedures required in this experiment were performed by Dr. F. C. Mann.

that a factor was operative in the treated group that was not operative in the group that was not treated. One can conclude only that the deterrent factor was supplied by the drug that had been given with therapeutic intent.*

Failures with promin.—Up to the time of writing we have treated, by the continuous daily administration of promin, 118 tuberculous guinea pigs. This total includes animals whose treatment began before the animals were inoculated and those whose treatment was delayed for as long as six weeks after the animals had been infected.† Although definite lesions of tuberculosis were present at necropsy in a considerable percentage of these animals, in only two instances did the amount and character of the tuberculosis present indicate that the drug had been without any therapeutic effect.

In one of the animals the treatment appeared to have aggravated the severity of the disease. This animal died 133 days after being inoculated subcutaneously with 0.0005 mg. of H37RV and had received promin daily with the feed during the entire period. At necropsy the amount of disease present in this animal was most impressive. There were a massive involvement of the spleen and a striking tuberculous pneumonia. The presence in the mononuclear cells of the liver and spleen of large numbers of acid-fast bacillary forms was indicative of hematogenous tuberculosis. As a matter of fact, the most striking feature of the tissues from this animal was the amazing number of acid-fast bacillary forms present, especially in the lung.

The second instance in which promin failed to exert any appreciable deterrent effect was encountered in study 6. The animal had received the usual dose of H37RV subcutaneously and forty-two days later the daily administration of promin was started. The treatment continued without interruption until the animal died 223 days after infection. Promin had been given for a total of 181 days. At necropsy, there were tuberculous lesions in the subcutis at the site of injection, the axillary lymph nodes were involved, the lungs, spleen and liver were affected extensively and there was hydrothorax. The amount and severity of the tuberculosis in this guinea

pig were equal to those observed in any of the control animals.

Why promin failed to influence the outcome of the disease favorably in these two instances is inexplicable.

Efficacy of promin against strains of tubercle bacilli other than H37RV.—Although we recognize the importance of knowing whether or not promin will be as effective against experimental infections established by other strains of mammalian tubercle bacilli as against H37RV, we have up to the time of writing but little information concerning this question. We have preferred to utilize most of our facilities with other phases of the problem. We have believed that it was first necessary to establish acceptable proof that chemotherapy could be and had been accomplished against an experimental tuberculous infection which without successful treatment would become inevitably a severe, extensive and fatal disease.

We have in progress at the present time an uncompleted experiment in which a relatively small number of guinea pigs was inoculated with a recently isolated "sputum" strain of tubercle bacilli. At the time of writing it is nearly seven months since the animals were inoculated and nine of the ten animals in the untreated or control group are dead. The amount of tuberculosis in the animals dead in the control group varied from moderate to severe but appeared sufficient in every instance to account for the death of the affected guinea pig. Of the nine animals in which daily treatment with promin was started forty-two days after infection, only two have died. Although on the basis of survival time it would appear that promin has been effective in opposing a tuberculous infection that has succeeded during the same period of time in killing all but one of the untreated animals, final conclusions must await the results of the examinations at necropsy of the survivors.

Final Considerations

In closing we should outline briefly what our studies actually have established and what the significance of certain of the findings may be.

1. The necropsy records and the histologic sections that have been prepared (and preserved) from every animal utilized in these experiments provide convincing morphologic evidence that the

*A more detailed description of this experiment will be found in the paper by Feldman, Mann and Hinshaw.¹⁰

†The group of twenty tuberculous guinea pigs (study 5) that were treated with promin daily every alternate week is excluded.

tubercle bacilli used to infect the guinea pigs which were subjected to chemotherapy were definitely and satisfactorily pathogenic. After inoculation even of relatively small doses, guinea pigs became sensitized to tuberculin and moderate to severe tuberculosis was present at the time of death in all the animals in the various untreated groups. The facts obtained from the animals in the control or untreated groups as well as from those groups that were treated with compounds that proved noneffective provide proof that the infecting bacteria we have used have been consistently and indisputably pathogenic.

2. Comparative studies have shown that of the various compounds tested promin is the most effective in combating an experimentally induced tuberculosis. That many of the compounds studied proved to be without recognizable therapeutic effect serves to emphasize the greater efficacy of promin.

3. It has been demonstrated repeatedly that, although the infection existed for six weeks before chemotherapy was started and although morbid changes characteristic of tuberculosis were actually present when therapy began, promin was capable of striking and unusual therapeutic effects. The vast majority of the treated animals lived longer than the controls. Many animals were apparently rid of all recognizable signs of the disease that had been seen in specimens for biopsy obtained when treatment began. When present after treatment, the amount and character of the disease were in most instances significantly unlike those present in the untreated controls. In the former the morbid changes were rather simple and usually were regressive or static rather than progressive and destructive such as characterized the lesions in the untreated controls.

4. From the facts that have accumulated regarding the ability of promin in most instances to cope successfully with an established, progressive and potentially fatal tuberculosis in the highly susceptible guinea pig, it would appear that the clinical trial of this drug is justified. Writing in 1932, Wells and Long mentioned the difficulty of combating tuberculosis successfully in the guinea pig and stated: "We may feel quite sure that a drug which cures the disease in the guinea pig, or even influences it favorably, would more certainly be beneficial in the much less susceptible human being."

The word "cure" should be used with reservations in regard to the chemotherapy of tuberculosis, since it is extremely difficult to establish with certainty that a "cure" has been accomplished. It is, however, less difficult to recognize whether or not the disease has been influenced favorably or its course arrested as a consequence of a therapeutic procedure. In our studies a considerable number of promin treated guinea pigs that were known definitely to have had lesions of tuberculosis when treatment began were without demonstrable signs of tuberculosis when examined months later at necropsy. Whether such animals have actually been cured of their tuberculosis in the sense that viable tubercle bacilli are no longer present is not certain. However, there can be no doubt that the disease had been influenced favorably, presumably as a consequence of the substance that was given with therapeutic intent.

When promin is tried in the treatment of clinical tuberculosis, the attempt should be made with the realization that the project will be difficult and the task long and arduous. It would be strange indeed if promin proved the most effective of the compounds likely to be studied for their chemotherapeutic effect in tuberculosis. Compounds that are less toxic and more efficacious are being sought constantly and the possibility of eventually securing a drug more satisfactory than promin is promising. An institution that would provide for the clinical trial of promin would be of course in a position to utilize other compounds as they become available. It should be emphasized, however, that no compound should be used in the chemotherapy of human tuberculosis until its safety and relative effectiveness have been established adequately by results obtained from animal experimentation.

SOME ASPECTS OF BLOOD STORAGE

MILTON LEVINE, M.S., Ph.D.
Minneapolis, Minnesota

THE widespread use of stored blood, serum and plasma in the treatment of anemia and shock necessitates frequent attempts at correlation of the results obtained with such therapy. Furthermore, the national emergency will tax our present transfusion facilities, and at the same time will extend the use of stored blood so that every clinician must be made aware of the principles, the hazards, and the advantages of the various procedures involved. The urgency of the problem seems to justify a discussion of the fundamentals even at the risk of boring by repetition.

Historically, serious consideration of the possibility of storing blood for transfusions began with the work of Rous and Turner²² at the Rockefeller Institute, who developed the first preservative solution. Their blood-dextrose-citrate mixture was tried on a practical scale by Robertson²¹ at the casualty clearing stations of the Third Army, B.E.F., during World War I. However, this work was forgotten until a group of Russian investigators⁹ began to employ stored blood in civilian cases. Their results, together with those obtained in the Spanish Civil War, and the favorable reports of its use for the first time in the United States at the Cook County Hospital^{17,8} have established the therapeutic status of stored blood for both military and civilian needs.

In the field of transfusions, the bacteriologist

is concerned with the preservation of the blood, and with the serological aspects of compatibility. Eliminating gross transfusion reactions due to incompatible groups is not his only problem, but it is an important one. Reactions due to incompatibility of the main blood groups (O, A, B, AB) are inexcusable, since correct grouping and cross-matching should eliminate entirely this type of reaction. Despite the simplicity of the tests involved, however, such reactions do occur. We have had one such non-fatal accident in the past two years.

Despite the elimination of reactions due to group incompatibility, reactions due to other factors still occur. Most of these reactions are minor, but occasional fatal ones have been observed. The reactions which may be encountered are as follows:

- | | |
|---------------------|-------------------|
| A. Mild: | B. Severe: |
| 1. fever | 1. nausea |
| 2. fever and chills | 2. vomiting |
| 3. chills alone | 3. hemoglobinuria |
| 4. urticaria | 4. jaundice |
| 5. rigor | 5. oliguria |
| | 6. stupor |
| | 7. uremia |

The reaction rate varies with the institution involved and with the interpretation of what constitutes a reaction. In general, however, it is customary to have a 5 to 10 per cent reaction rate of the minor varieties, and less than 1 per cent of

From the Department of Bacteriology and Immunology, University of Minnesota, Minneapolis, Minnesota.

the more severe forms. DeGowin,³ who has contributed much to the knowledge of the subject by his research on the preservation and administration of stored whole blood, has managed to reduce his total reaction rate to 5.6 per cent. Other workers have been less fortunate.

What are the factors influencing the rate of reactions?

Pyrogens.—The work of Seibert²⁴ and others has demonstrated that numerous bacteria, mostly nonpathogenic, will grow in solutions, in rubber tubing, on glass containers, and in distilled water. These bacteria will give rise to substances (pyrogens) which are not inactivated by sterilization, and which cause chills and fever when injected intravenously. They are undoubtedly responsible for many reactions we obtain from intravenous solutions, and from transfused blood or its derivatives. DeGowin⁵ found that rubber tubing which was allowed to drain for eighteen hours before sterilization was responsible for a high incidence of reaction in blood transfusions coincidental with a rise in the number of reactions following the administration of intravenous fluids. To prevent a similar situation, all apparatus must be rinsed in freshly prepared distilled water, and together with the solutions, sterilized immediately after preparation.

Hemolysis.—It is difficult to assess the rôle of hemolysis as a cause of transfusion reactions. It has been conclusively demonstrated by DeGowin⁶ and others that the amount of hemoglobin in the supernatant plasma increases with the increase in the time of storage. Despite this fact, DeGowin,³ Muether¹⁴ and others have found no significant differences in the number of transfusion reactions caused by blood stored for varying periods of time up to thirty-eight days. If it were demonstrated (which it is not) that old blood gives a larger percentage of reactions than freshly drawn blood, it would not necessarily mean that the hemoglobin is at fault, since a number of other products are formed by the disintegrating cells, along with the hemoglobin. It is our opinion that moderate hemolysis, in itself, is unimportant as a cause of reactions. It is, however, of importance in the therapy of conditions requiring red cell replenishment. We must consider, therefore, such factors as cell fragility, hemolysis, and donor cell survival in the recipient.

Muether¹⁵ has thrown some light on the situation. He demonstrated that mechanical fragility of the cells increases rapidly up to five days after storage, and then stabilizes at a constant level for the next thirty days. Bull and Drew¹ found the red cell count to remain about the same for fifteen days, and then to decrease by from 1 to 1.5 million cells by the end of one month. Philip Levine¹³ has contributed an interesting and pertinent observation on the survival of transfused red cells. Identifying the donor cells by means of the M and N factors, he found that cells stored three, ten or fourteen days survived in the recipient for eighty, sixty or twenty days, respectively, as compared with cells of fresh blood, which were still present in the recipient ninety-five days after transfusion. Thus the patient's syndrome must be considered in determining the importance of the length of storage of the blood to be administered.

To cut down on the rate of deterioration of the cells, various methods have been suggested. Of the greatest importance is the temperature at which the blood is stored since rate of deterioration increases with an increase in temperature. Most laboratories, including our own, keep blood at from 2 to 8° C. Blood kept at room temperature will deteriorate rapidly within twenty-four hours. Scudder²³ has introduced a special bottle which exposes a minimum of blood surface to the air, and has also advocated the use of an atmosphere of CO₂ to prevent deterioration due to oxygen exposure. A number of other workers have demonstrated that agitation increases the rate of disintegration.

Of importance, also, is the solution in which the blood is collected. DeGowin⁶ demonstrated the superiority of a dextrose-citrate-blood mixture over a plain citrate mixture as a preservative solution. The difference in the hemolysis rate, however, only becomes significant after the blood has been stored for ten days. We have not used this preservative at the University Hospitals because all the blood administered is less than ten days old. The slight advantage of the dextrose solution in blood stored for less than ten days is counterbalanced by the increase in the volume stored (650 c.c. of 5.4 per cent dextrose, 100 c.c. of 3.2 per cent sodium citrate, and 500 c.c. blood are contained in the mixture, a total of 1,250 c.c.). In addition, the separate autoclaving of the citrate and the dextrose requires twice as

many flasks and doubles the amount of preliminary work in preparing the collecting apparatus. All this makes it advisable for us to use citrate alone as a preservative solution, and necessitates the use of the most recently drawn blood for those patients requiring red cell replenishment.

Chemical Changes.—Scudder²³ has attached great significance to the potassium which diffuses out of the erythrocytes during storage. He has shown that the potassium level in the supernatant increases progressively with time. Practically, however, DeGowin⁴ has demonstrated that potassium is not important in transfusions of stored blood. I quote his clear conclusions based on actual test administration of bloods with high potassium levels:

The high plasma potassium content in blood preserved for thirty days is not toxic when the blood mixture is transfused into human beings at velocities of less than 43.3 c.c. per minute. The concentrations of plasma potassium encountered in blood stored for one month are not high enough to cause significant increases in the serum potassium of the recipient.

Muether¹⁶ confirms this opinion and cites as further evidence the use of stored blood in two cases of Addison's disease in crisis without a reaction resulting.

Rhoads and Panzer²⁰ and Quick¹⁹ have found that prothrombin of stored blood diminishes on standing and they suggest that such blood is inferior to fresh blood in controlling bleeding in jaundice.

Scudder²³ has demonstrated a change on storage in the electrophoretic pattern of the blood proteins. Other workers have shown a decrease on standing of the leukocytes and complement. All these factors must first be shown to be necessary before we can even consider them as important in specific diseases. At present, they seem to be insignificant in the treatment of shock, and only of theoretical significance in other conditions.

Bacterial Contamination.—The reports of recent efforts to supply blood for the present emergency indicate that bacterial contamination is the single most important factor to be controlled in eliminating transfusion reactions. Only a completely closed system from donor to recipient will prevent contamination, and such a system is manifestly impractical even if possible. It then

becomes necessary to minimize exposure of the blood to bacteria, which may come from the air or from contaminated surfaces. Secondly, it becomes essential to prevent the multiplication of bacteria which may enter the blood despite all precautions.

To minimize exposure, the blood bottle should be capped immediately after collection of the blood, and should not be opened unnecessarily. It is important that the blood be administered as soon as possible after it has been filtered through gauze in an open room. These things should be considered when blood is administered or drawn. The insertion of the hypodermic needle into the donor's vein offers an opportunity for the introduction of bacteria from the well contaminated skin. Thorough application of the bi-chloride-acetone-alcohol solution (Novak's solution) before insertion of the needle will help eliminate this step as a source of bacterial contamination.

The filtering process is not advisable from the point of view of sterility, but until further studies demonstrate a simpler and safer method for eliminating fibrin clots, this procedure will have to be tolerated. Citrate is not a perfect anti-coagulant, and clots will form.

Novak¹⁷ first described the use of sulfanilamide in the preservation of stored blood. He found that the bacteriostatic properties of this drug in amounts "compatible with intravenous dosage" inhibited the growth of organisms normally found as contaminants in the blood. Before the routine use of this drug at the University Hospitals, contaminated bottles were not uncommon. Since its introduction (0.1 gram for every 500 c.c. of blood), there has not been a single contaminated sample in more than 5 million c.c. transfused in the past three years. Every blood reported to cause a reaction has been tested bacteriologically with consistently negative results. It must be emphasized that all the blood was less than ten days old, and during this period the bacteriostatic action of the drug is assisted by the leukocytes and natural bacteriocidal substances in the blood. In older bloods, the disintegration of these factors may make the sulfanilamide less effective.

Iso-antibodies.—The importance of isohemagglutinins in donor blood as a cause of reactions is a problem which still remains to be solved. There is a large amount of work indicating that blood from a universal donor is harmless when

given to a patient of any blood group. More recently, experience derived from the use of plasma and serum has added to the evidence indicating that the isohemagglutinins in administered blood, plasma, or serum are of negligible importance. Nevertheless we must consider isolated instances where the titer of anti-A and anti-B agglutinins has been extremely high, reaching 500 or more. Gesse¹⁰ has published the most complete study on this phase of transfusion reactions. He described forty-six cases of shock following administration of universal blood; twenty of these were fatal. New York State has also recognized the possibilities involved and adopted a sanitary code regulation requiring group O blood to be titrated before use in order to eliminate bloods with a high titer of isohemagglutinins. To counteract the deleterious effects of universal blood, Witebsky and his co-workers²⁷ have introduced antigenically specific A and B substances which neutralize the homologous hemagglutinins when added to the whole O blood. We have used these substances on fifteen patients and have noticed no untoward reactions on the administration of the treated universal blood. Titration of the bloods before and after adding the specific substances revealed the anti-A and anti-B agglutinins in group O blood were almost completely removed. Further work is necessary to demonstrate conclusively the dangers attached to the use of group O blood, and the benefits to be derived from Witebsky's substances. The use of universal blood in infants and children is more to be questioned than its use in adults, since the dilution factor is not so great in young children.

In 1940, Landsteiner and Wiener¹¹ demonstrated a factor in human cells which corresponds to a similar substance in the erythrocytes of the Rhesus monkey. This factor (Rh) is undoubtedly responsible for fatal reactions in humans after repeated transfusion.²⁶ In this respect, it is like the M and N factors, but unlike these, it is not easily demonstrated in a cross-matching. In a later paper¹² Wiener has described a method for detecting the presence of the Rh factor by the use of guinea pig antiserum. Whether the same method can be used in a cross-matching remains to be seen. It may be necessary to test each blood for Rh factor before transfusion to prevent the administration of Rh positive blood to Rh negative patients, but at present the materials for such a routine test are not available. The

guinea pig is not an entirely satisfactory animal, according to Wiener, and a better animal is needed before the antiserum may be used routinely.

The demonstration of the Rh factor suggests the possibility of other similar but as yet unknown substances being responsible for reactions in repeated transfusions. Further experimental work is obviously necessary.

Allergic Factors.—Frequently, following a transfusion, recipients have demonstrated symptoms indicating an allergic response to the transfusion. The most common sign is a generalized urticaria. DeGowin³ could find no relationship between this reaction and a history of allergy in the patient; however, this does not disprove the allergic nature of the condition. Many have recognized the theoretical possibilities of the transfer of allergens in the transfused blood. This has been responsible for the requirement of many hospitals that fasting donors be used exclusively. Such transferred allergins would give an urticaria if associated only with a skin sensitivity, but no other allergic manifestations. Under such a condition, a history for allergy might well be negative.

At the University Hospitals we have not required fasting from donors. This would be impractical, since all the donors are friends or relatives of the patients, and have been difficult to obtain even without prerequisites. The imposition of fasting previous to drawing blood would cut our present supply considerably. However, if a new source of supply is obtained, such a procedure should be endorsed, although the time factor would be arbitrary at best. At the suggestion of Dr. C. J. Watson, we have recently inaugurated the practice of marking the fasting time on the label of the blood bottle. This has been done so that patients with allergic histories may receive bloods drawn as long as possible after a donor's meal.

Blood Bank at the University Hospitals

Blood is drawn by interns of the individual services and given to the blood bank. This blood is credited to the service. There is as much blood in the bank as is credited to all the services. Blood is released from the bank upon receipt of a written request for a cross-matching with the patient's serum. It is given out regardless of the

individual from whom it was drawn or the service to which it is credited.

The blood is kept at from 2 to 8°C., and is labeled as follows:

Group _____ Date _____
 For _____
 From _____ Age _____
 Doctor _____
 Space for Laboratory _____
 Kline _____ Date _____
 Fasting time _____

Before administration, each blood is cross-matched with the patient's serum for agglutination and hemolysis. The agglutination test is run by using a drop of a suspension of the donor's cells plus a drop of the patient's serum. This is incubated on a slide for fifteen minutes at room temperature, and read as to whether agglutination or rouleaux has occurred. The hemolysis test consists of combining equal portions of patient's serum and donor cell suspension in a test tube at 37°C. for one hour. The test is then read as to hemolysis or non-hemolysis. We run both tests as a double check, and because some workers² have suggested the presence in incompatible bloods of isohemolysins independent of isohemagglutinins.

Bloods are not used if agglutination, rouleaux or hemolysis occurs. The detrimental effect of rouleauxed blood has never been demonstrated. Many bloods require numerous cross-matchings because of rouleaux formation, and as a result much extra work is involved.

A Kline diagnostic test for syphilis is run on each blood in the bank. The sensitivity of this test is thought to be sufficient for this purpose. We have numerous false positives, which are checked with the Wasserman and Kahn tests before being used. A 1+ Kline with a negative Wassermann and Kahn is considered safe for use. A sample showing a 2+ Kline confirmed by the State Board of Health is not used. There is every indication that the possibility of transfer of syphilis by stored citrated blood is almost negligible after twenty-four hours of storage, and impossible after storage for three days. Experimental work²⁵ has demonstrated that virulent spirochetes introduced into stored blood are eliminated in from forty-eight to seventy-two hours. Considering the number which might be present in circulating blood, and the fact that most of

our blood stands for at least twenty-four hours, the possibility of a Kline negative blood causing syphilis in the recipient becomes remote, although not impossible.

Until recently we ran sterility tests on all bloods in the bank at the end of five and ten days' storage. Since these were consistently negative (over a two-year period), we eliminated the test except on occasional bloods. We have done this because the test for sterility itself introduces a source of contamination. Tests of all bloods causing reactions have failed to demonstrate a single contaminated specimen.

A few words about the apparatus are necessary for those who are interested in the practical aspects of the problem. Until recently we used the Abbott solution bottle. Priorities interfered with the production of the aluminum caps used for final storage of these flasks and we had to switch to a new container put out by the Upjohn Laboratories. The latter apparatus uses a square bottle which conserves storage space, and a plastic cap for final storage. It has the disadvantage of a complicated "well" for drawing the blood, which introduces another piece of apparatus to be cleaned. However, it is, in our opinion, the most satisfactory apparatus available at present.

During the past two months, we have attempted to collect data for a statistical study of the factors involved in transfusion reactions. It is too early to give a complete analysis of the data, but some of the results so far obtained are of interest. Of 377 consecutive bottles of blood transfused, the age of the blood is given in Table I.

TABLE I

Age of Blood in Days	Number of Bottles Given
1	94
2	57
3	63
4	46
5	36
6	29
7	26
8	16
9	7
10	3

Of the total, approximately 80 per cent were five days old or less. This would indicate, as we have stated previously, a rapid turnover of blood. The reaction rate of a consecutive series of 522 whole blood transfusions was 4.2 per cent. Of

the twenty-two bottles causing a reaction, eight gave repeated reactions in three patients. One patient developed chills and a rise in temperature after each of four bottles administered. Two patients developed these same symptoms after each of two bottles of transfused whole blood.

If we compare this with the reaction rate of 149 plasma transfusions (22,350 c.c.), we find that the plasma has an advantage, which, however, must be strengthened by a larger and statistically more reliable series before any definite comparison can be made between the whole blood and plasma. The reaction rate in the plasma series was 2.0 per cent, three of the 149 transfusions giving rise to reactions.

The types of reactions encountered are shown in Table II.

TABLE II. REACTIONS FROM WHOLE BLOOD

Type of Reaction	Number of Patients
Chill and fever.....	10
Chill	9
Spasms and chill.....	1
Edema	1
Itching	1

In addition to the above symptoms, three patients complained of nausea, one of back pain, one of a "prickly feeling" in the back, and four of headaches. Only two of the twenty-two reactions following the transfusion of whole blood involved heterologous groups. In these cases, group O blood was given to a group A patient. That this was not responsible for the reaction is indicated by the fact that both of these reactions were in the one patient who also reacted adversely to each of two homologous bloods.

Each time a reaction occurred, the blood was cross-matched again, and tested for sterility. In all cases, the results were negative. The fact that some individual patients react with many bloods at different times would indicate that the reaction is associated with some condition in the recipient. That this may be a developed immunity to some factor in the donor blood is suggested by the fact that many of the repeated reactors have had previous transfusions. In the one case with four reactions to four different bloods, the patient was suffering from aplastic anemia, and had been transfused many times before being studied in the present series.

It is beyond the scope of this report to give a

comprehensive discussion on the use of plasma and serum as well as whole blood. Within the last year we have been supplying plasma on demand to all services. The plasma is drawn off whole blood which has stood in the refrigerator until the red cells have settled to the bottom. The plasma is syphoned off the cells and is used immediately after preparation.

All precautions for sterility are observed, but we realize that only a closed system would be entirely satisfactory. Since this is impractical and since filtering of plasma is a task requiring facilities not available to us, we have resorted to the use of freshly drawn plasma transferred in a closed room under a bactericidal ultra-violet lamp.

It is our opinion that this method of obtaining plasma is satisfactory for the present demands of the average hospital. If storage is required, a new problem arises. The simplest method of storing serum or plasma is by rapid freezing and storage at subzero temperatures. We have tried this method on plasma, with the aid of the Human Serum Laboratory, and have found it satisfactory providing the niceties of the freezing and thawing procedure are observed.

If the plasma is not frozen in a shell in CO₂ ice, it yields fibrin clots when thawed out. If it is so frozen, kept at subzero temperatures, and thawed out at 37° C., the final product is entirely satisfactory and gives rise to no reactions.

It must be remembered that frozen plasma will permit the growth of bacteria after the thawing process begins, so the plasma should be used almost immediately after thawing. There is a hazard of contamination in this type of preservation which must always be kept in mind. A more satisfactory way would be to filter the plasma before freezing. The most desirable procedure involves the filtering, freezing, and drying of plasma and serum, which method will eventually replace all others when facilities are available.

The serum versus plasma controversy is one which has more of a partisan than a scientific basis. There is no reason to believe serum to be more toxic than plasma as is claimed by the proponents of the use of the latter. Nor is the evidence of the serum group any more reliable when directed against the use of plasma. It would seem from an examination of the figures on both serum and plasma transfusions that both are better than whole blood in that they cause

fewer reactions. There is, however, no statistically sound information available as to which form (dry or wet, frozen or unfrozen) of serum or plasma is preferable.

No doubt much has been omitted in the above discussion, but it is a fault inherent in so comprehensive a field. We have tried to point out that a fundamental scientific approach to the subject of blood storage and transfusion is essential if we are to get rid of the many superstitions associated with it.

Many other questions arise, and many problems remain to be solved. It is a step forward to recognize their existence.

GASTROJEJUNOCOLIC FISTULA

Report of a Case

RAYMOND F. HEDIN, M.D.

Red Wing, Minnesota

GASTROJEJUNOCOLIC fistula presents a formidable surgical problem. Czerny was the first in 1903 to report a case of gastrojejuno-colic fistula. Recent reports¹ indicate that there have been 322 such cases recorded in the literature. Undoubtedly, there are many more which have not been reported. Because of the various procedures which have been used to correct this very unfavorable condition, it is believed worth while to report a case successfully treated by a two-stage method.

Gastrojejuno-colic fistula is one of the most dreaded of all complications resulting from gastro-enterostomy. It has been stated that because of the popularity of gastro-enterostomy during the

past fifty years, that this condition has become increasingly more common. This communication is a result of ulceration between the stomach, jejunum and colon and is usually secondary to gastro-enterostomy, but it is also known to be associated with malignancy.⁴

The statistics show the presence of anastomotic ulcers to vary considerably. Some men are of the opinion that marginal ulcers occur in from 1 to 3 per cent of cases.⁸ However, others have reported the frequency of marginal ulcers as high as 35 per cent. The occurrence of gastrojejuno-colic fistulas is overwhelmingly more common in the male than in the female. This is due to the preponderance of peptic ulcers in the male. This complication is found to occur most frequently in the third to fifth decades of life and is found in

From the Interstate Clinic, Red Wing, Minnesota. Read before the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 29, 1941.

patients who are in the so-called peptic ulcer diathesis group.³ The appearance of such fistulas are reported² to have occurred from six weeks to twenty-one years following a gastro-enterostomy.⁷

Symptoms

The most pronounced symptoms of gastrojejunocolic fistulas are: (1) indefinite abdominal pain which may be similar to that of a peptic ulcer or at times may be entirely absent; (2) persistent diarrhea resistant to medication and a watery, alcoholic stool which contains varying amounts of undigested food; (3) rapid and progressive weight loss, despite a good appetite; (4) eructation characterized by a foul odor; and (5) at times the vomiting of fecal material.

Diagnosis

The diagnosis is often easily made, but at times may be very difficult and tests the diagnostic acuity of the surgeon. The use of the barium meal and barium enema are of definite value in establishing the diagnosis of a communication between the upper and lower reaches of the gastrointestinal tract. Once the diagnosis is made, prompt surgical treatment is indicated.

Treatment

The treatment of gastrojejunocolic fistulas consists of prophylactic treatment. This should be directed towards a strict medical management of all patients who have had operations for a peptic ulcer.

To operate on a patient with a gastrojejunocolic fistula without rehabilitation invites disaster. Each case makes its own demand on the judgment of the surgeon. These patients are usually suffering from emaciation, dehydration, chemical imbalance, and a lack of vitamins. Because of the extreme debility of such patients, various surgical procedures have been reported, the mortality ranging from 25 to 63 per cent. However, with a careful pre-operative regime the mortality can be considerably reduced.

Pfeiffer^{5, 6} has recently advocated the use of a colostomy prior to the restoration of the gastrointestinal tract. He stated that the cause of the rapid diarrhea and chemical imbalance in these cases is the regurgitation of colonic material into the stomach, and this causes rapid peristalsis through the small intestine with little or no

absorption of the food. He believes that to sidetrack the fecal stream and thereby not allowing the feces to pass through the portion of the colon involved in the fistula, has a three-fold purpose: (1) prevent feces from regurgitating into the stomach; (2) allows edema and the adjacent inflammation in the tissues to subside; (3) protects the suture line in the repaired colon.

In a recent survey, Pfeiffer has found that in fifteen cases, the mortality has been but 6 per cent when a preliminary colostomy was done. The procedure is justifiable and, as stated above, should be carried out as a first stage to rehabilitate these patients in order that they will be better able to stand the more formidable surgical procedure of restoration of the gastro-intestinal tract or a partial gastric resection, if necessary. Bloc resection of the parts involved in the fistula has often been necessary in treating gastrojejunocolic fistulas.

The case which I am to report has utilized the principle advocated by Pfeiffer, but instead of the use of a colostomy, an ileostomy was done because it was thought that an ileostomy is a less formidable procedure than a colostomy and that it precludes the necessity of crushing the spur as is done in Pfeiffer's method. Also, there is not an undue amount of fluid lost through an ileostomy.

Case Report

J. F., male, aged fifty-four, stated that he had had a gastroenterostomy five years ago and had remained well until two months previously, when he developed a diarrhea, consisting of ten or twelve bowel movements a day. The patient stated that he had been belching up foul smelling gas from his stomach for the past six weeks and that he had lost twenty-five pounds over this period. The laboratory work was as follows: The urine was essentially normal, hemoglobin 90 per cent; red blood count 4,630,000, white blood count 11,700. Differential count of neutrophils 37, lymphocytes 61, large mononuclears 1 and eosinophils 1 per cent. The blood Wassermann was negative. Gastric analysis showed the acidity to be within the upper limits of normal. The feces were found to be negative for occult blood.

A sigmoidoscopic examination was made for a distance of 24 cm. which disclosed a rather injected mucosa with a large amount of undigested food material present. A barium enema was given which showed the barium to immediately enter the stomach as well as the small intestine (Fig. 1). Also, barium by mouth was found to enter almost immediately the colon as well as to go rapidly through the small intestine. A diagnosis of gastrojejunocolic fistula was made.

On January 2, 1941, a knuckle ileostomy was done through a McBurney incision (Fig. 2), a glass rod being used to anchor the loop of ileum. No sutures were taken and the wound was packed with vaseline

of the jejunum. Sulfanilamide crystals were placed on the suture lines.

The patient was given a blood transfusion as well as perenteral vitamins. His chemical balance was re-

Fig. 1. Barium enema entering stomach and small intestines.

gauze. The ileostomy was opened on the second day and the patient immediately responded to the treatment. The diarrhea ceased and he had but one bowel movement by way of the rectum during the ensuing month. The patient no longer had eructations of foul material and his appetite increased. The patient was given perenteral vitamins in large doses and placed on a high-caloric diet. He was discharged on January 15, 1941. When he was next admitted on February 27, 1941, he had gained forty-three pounds. The gastrojejunal fistula was then repaired, the fistula measuring about 2 cm. in length and 1 cm. in diameter. The indurated tissue was removed and the defect in the colon was closed transversely with chromic catgut and supplemented with interrupted silk mattress sutures. The posterior gastro-enterostomy was taken down (Fig. 3). The jejunum was closed with three layers, two layers of catgut, and a third layer of interrupted silk mattress sutures. The posterior wall of the stomach was likewise closed by a similar method. The lumen of the jejunum was somewhat compromised by this type of a suture and it was thought that the lumen of the jejunum would be inadequate to carry food to the lower reaches of the intestine. For this reason, a side to side anastomosis in the jejunum—ajejuno-jejuno anastomosis—was then made, by-passing the stenosed portion

Fig. 2. Illustration showing site of pathologic lesion and ileostomy.

established by means of saline and the patient was discharged on March 26.

The patient continued to improve. There had been no undue fluid loss during the existence of the ileostomy. He became adjusted to wearing a colostomy bag and it was with some insistence that the patient allowed the ileostomy to be closed. He stated that he was perfectly comfortable and because of the inadequacy of plumbing in rural Minnesota in the winter time, he saw no particular reason to have the fecal stream pass in the normal way.

On July 3, 1941, the ileostomy was closed by suturing the defect transversely with chromic catgut sutures and reinforcing with interrupted silk mattress sutures. Sulfanilamide was placed over the suture line and the abdomen closed in layers. The patient was discharged on July 13, 1941.

The follow-up on this patient showed no activation of his former duodenal ulcer and the barium passed normally through the stomach and the remainder of the gastro-intestinal tract. A recent check-up found this patient to be enjoying good health.

Discussion

The use of an ileostomy to divert the fecal stream was followed by marked improvement in the patient as well as subsidence of the diarrhea. The use of an ileostomy rather than a colostomy proved beneficial and is thought to be an easier surgical procedure, and can be done with practically no mortality. The use of stage operations such as this allows, as Pfeiffer has stated, for improvement of the patient, allows the inflammatory reaction in the region of the fistula to subside, and also serves as a safeguard against blow-

ing out the suture line in the colon. As has been stated in numerous articles, patients suffering from this condition, the so-called ulcer diathesis, should in certain cases have a partial gastric resection so as to preclude the possibility of any

3. The merits of stage operations utilizing Pfeiffer's principle of diverting the fecal stream so as to allow the patient to be rehabilitated before restoration of the gastro-intestinal tract is attempted, has been described.

Fig. 3. Illustration showing repair of transverse colon and restoration of continuity of gastro-intestinal tract, also site of jejunostomy. Insert: Site of ileostomy.

further ulcer formation. However, it is felt in this case that because of the age of the patient that his acid will gradually decrease, thus lessening the chances of recurrence of his original duodenal ulcer. It is not thought that a procedure such as a gastric resection is warranted at this time.

Summary

1. A case of gastrojejunocolic fistula is reported.
2. Ileostomy is efficacious in diverting the fecal stream.

In planning the battle strategy against tuberculosis we need to keep in mind important traits or characteristics of the enemy. We have had a recent taste of dealing with an enemy of slimy cunning, hiding under a cloak of diplomatic conversations. Tuberculosis is another such foe; sneaking, insidious and stealthy. No policy of appeasement or of diplomatic negotiation will accomplish results. Either this must be an "all-out" war or it will be one of the comic opera variety. Another characteristic of this foe is the habit of striking hardest where resistance is least. To conquer such a foe we must be fully prepared, well armed. We must attack on a wide front and not merely by launching two-man submarines.—MATHEW WOLL, *Pennsylvania's Health*, Feb., 1942.

MITRAL STENOSIS AND PARALYSIS OF THE LEFT RECURRENT LARYNGEAL NERVE

CHARLES H. SCHEIFLEY, M.D., and HARRY L. SMITH, M.D.
Rochester, Minnesota

CONVINCING proof is yet wanting that paralysis of the left recurrent laryngeal nerve may be caused by mitral stenosis. Mitral stenosis is a common clinical condition. However, in only a rare case of mitral stenosis is any evidence exhibited of an associated laryngeal paralysis.¹ If there is a cause and effect relationship between these two conditions, it is difficult to understand why paralysis of the left recurrent laryngeal nerve is seen so seldom in a condition as common as rheumatic mitral heart disease. Kelly² suggested that perhaps the association of left laryngeal paralysis with mitral stenosis was merely a coincidental occurrence. It is a well known fact that in many cases of laryngeal palsy there is no clue whatever as to the etiology.³ New and Childrey⁴ presented 194 cases of paralysis of the left recurrent laryngeal nerve; in sixty-seven of these, or 63.8 per cent, the condition was of unknown cause. Had mitral stenosis been present in any of these sixty-seven cases, it would have been logical to assume that laryngeal palsy was the result of the associated mitral stenosis.

To add to the uncertainty, several different mechanisms have been postulated to explain how mitral stenosis may cause paralysis of the left recurrent laryngeal nerve. Ortner⁵ in 1897 first described the occurrence of left laryngeal paralysis in association with mitral stenosis. The cause of the laryngeal palsy, he said, was pressure on the recurrent nerve by the dilated left auricle which compressed the nerve between the auricle and the arch of the aorta. Herrick⁶ and later Grabower⁷ subscribed to this view, but Fetterolf and Norris⁸ in 1911 showed rather conclusively that pressure of the left auricle against the arch of the aorta was anatomically impossible. They found that in mitral stenosis the dilated left auricle pushed the pulmonary veins upward; these veins, in turn, exerted pressure on the superiorly located pulmonary arteries. The already dilated pulmonary arteries compressed the recurrent nerve between themselves and the aorta and the aortic ligament. King, Hitzig and

Fishberg¹ reported three cases of hypertensive and arteriosclerotic heart disease in which an associated left laryngeal paralysis was present; laryngeal palsy developed in two of the cases after coronary occlusion. They explained the paralysis as being caused by dynamic compression of the recurrent laryngeal nerve between the pulmonary arteries and the arch of the aorta. The reason laryngeal palsy was found so rarely in cases of mitral stenosis, they suggested, was that the anatomic conditions necessary for compression of the recurrent laryngeal nerve by the pulmonary arteries are fulfilled in only a small proportion of persons.

Hall, Ferrier and Permewan⁹ and Kraus¹⁰ believed that the left recurrent laryngeal nerve becomes paralyzed as a result of traction exerted on it by the aortic arch, which is dragged upon by the enlarged heart. Adam¹¹ and later Langeron¹² stated that laryngeal nerve palsy did not occur in heart disease unless there was some associated inflammatory condition in the mediastinum or in the pericardium.

Thus, five different mechanisms have been described to show how the dilated heart in mitral stenosis may cause paralysis of the left recurrent laryngeal nerve and none actually has been proved.

This report is based on ten cases in which paralysis of the left recurrent laryngeal nerve was associated with mitral heart disease. The records of 223 patients who had left laryngeal palsy were examined in the course of this study. In all cases, the diagnosis of paralysis of the left recurrent laryngeal nerve had been made by a qualified laryngoscopist. There were ninety-one cases, or 41 per cent, in which no cause for the laryngeal paralysis could be found. Had a mitral cardiac lesion been discovered in any of these cases of unknown etiology, the laryngeal palsy probably would have been considered to be a result of mitral stenosis. Actually, two patients who did have mitral stenosis were included in this group. They represented well-compensated subclinical conditions in which very little cardiac enlargement was present, and we considered the

From the Mayo Foundation. (Scheifley, Fellow in Medicine) and the Section on Cardiology (Smith).

mitral stenosis to be merely coincidental. The condition of these two patients previously had been diagnosed as laryngeal palsy secondary to mitral heart disease.

Paralysis of the recurrent left laryngeal nerve among the ten patients mentioned herein was considered to be the result of mitral heart disease. The average age of the patients was thirty-eight years. There were six females and four males. Two patients had auricular fibrillation. All ten patients were suffering from well-advanced mitral stenosis and were found to have markedly enlarged hearts by clinical and roentgenologic examination. More significant, however, was the fact that in all but two cases recurrent laryngeal palsy had occurred during a period of cardiac decompensation. The other two patients had a marked reduction in cardiac reserve, but had not as yet experienced actual congestive failure.

Assuming that left laryngeal palsy has only a fortuitous relationship to the presence of mitral stenosis, we should expect mitral stenosis to be found no more frequently among patients suffering from left laryngeal palsy than among patients taken at random. We found, actually, among the 223 records of left laryngeal palsy that were reviewed, ten cases of mitral stenosis, or an incidence of about 5 per cent. A study of the general records in the clinic revealed that mitral stenosis is present in the clinic population as a whole in only about a half of 1 per cent of cases, so that we found mitral stenosis to be relatively ten times more frequent among patients who had paralysis of the left laryngeal nerve than it was in the general control group. Similarly, it could be argued that if the relationship of left laryngeal palsy and mitral stenosis were merely circumstantial, then mitral stenosis would be found at least half as frequently among cases of *right* laryngeal palsy as among cases of *left* laryngeal palsy. (Paralysis of the right recurrent laryngeal nerve occurs about half as frequently as paralysis of the left recurrent laryngeal nerve).⁴ On the other hand, if the rationale on the basis of which this inquiry is being made has validity, namely, that in the presence of mitral stenosis and the

resultant enlargement of the right portion of the heart, pressure is exerted on the left recurrent laryngeal nerve which results in laryngeal paralysis on that side, then mitral stenosis should occur more than twice as frequently in instances of left laryngeal palsy as in cases of right laryngeal paralysis. As a matter of fact, whereas we found that nearly 5 per cent of the patients suffering from paralysis of the left recurrent laryngeal nerve had coexisting advanced mitral cardiac disease, no instances of clinical mitral stenosis were found in any of the cases of right laryngeal palsy which were reviewed.

Summary and Conclusions

Well-advanced rheumatic mitral cardiac disease was found in ten of 223 cases of paralysis of the left recurrent laryngeal nerve, whereas no instances of advanced mitral cardiac disease were encountered among patients who had right laryngeal palsy. Mitral stenosis was found to be relatively ten times as frequent among patients who had paralysis of the left recurrent laryngeal nerve as it was in a general control group. These observations suggest that there is a causal relationship between the enlarged heart present in mitral stenosis and paralysis of the left recurrent laryngeal nerve.

CLINICAL-PATHOLOGICAL CONFERENCE

◆ MINNEAPOLIS GENERAL HOSPITAL ◆

Frank C. Andrus, Pathologist

Presentation of a Case

DR. FRANKLIN MOOSNICK: The case is that of a chemist, forty-nine years old, who was admitted to the Minneapolis General Hospital on July 29, 1941. His present complaints go back to the beginning of 1941 when, for the first time in his life, he began to develop signs and symptoms of right and left heart failure. At that time, he was taken to one of the private hospitals and kept there for three weeks. He was treated by his physician with digitalis and became compensated during that period of time and was able to go home. He insisted that he had followed his cardiac régime religiously at home, but two months later he began to develop signs of mild heart failure. His most distressing complaint was severe nosebleeds which he could not control at home. He stated that his blood pressure was 240 systolic. A month or so later he became decompensated and was again hospitalized in June, 1941. He went home and some two or three weeks before admission, early in July, 1941, he again became decompensated and had the additional symptom of spitting up blood-tinged sputum. His past history was not remarkable. He had had rheumatic fever at the age of twelve years. He had had no episodes of rheumatic fever since then although he had had frequent sore throats which were followed by quinsy. He had some difficulty with his eyes which took the form of blurring of vision, spots before his eyes, headaches, and dizziness. These symptoms dated back to a year or eighteen months before admission to the hospital. His only other complaints were frequency and nocturia with day and night urinations being about five times each.

Physical examination revealed a mildly dyspneic and slightly cyanotic man. The pertinent physical findings included the signs of left heart failure with râles in the bases and a slight amount of free fluid in both bases. The cardiac dulness measured 12 cm. to percussion on the left. The rhythm was grossly irregular. The blood pres-

sure was 170/118. The liver was enlarged. There was two plus edema of the ankles. The scrotum, at that time, was markedly thickened and swollen, the thickening being more than just edema. It was covered with flat, purple lesions which later on skin consultation were found to be angiokeratomata.

Laboratory Findings: There was slight leukocytosis, 13,900, with a normal distribution of the leukocytes. The hemoglobin was 72 per cent and the erythrocyte count was 5,200,000. The blood urea nitrogen was 23 mg. per cent. The urine revealed a maximum concentration of 1.019; it contained three plus albumin, occasional casts, a few white cells, and to as high as 20 red cells in all specimens. Serologic tests for syphilis were negative.

He was placed on the usual cardiac régime with limited fluids, diuretics, et cetera. He responded with a good diuresis. In the course of the first week or ten days, he lost twenty-five pounds in weight. Three or four days after admission, his temperature rose to 103 degrees and he developed a leukocytosis of 18,000. The chest was clear on physical and x-ray examination. No focus of infection could be found. It was during the exceedingly hot part of summer then and it was the opinion of the staff that he was suffering from heat retention secondary to marked diuresis and limited fluids. The fluids were increased slightly and his temperature fell. During the course of his management, he showed signs of digitalis intoxication and developed an acute heart block with A-V disassociation. Extra-systoles were heard. He became cyanotic and the heart rhythm was irregular, however, he did well on a cardiac régime. The heart rate later became regular and slow. He was transferred to a rest home for prolonged rest and convalescence.

He was again seen on the Medical Service on November 18, 1941. Physical examination at that

time was essentially negative. He was well compensated but the hypertension persisted. He now had hematuria in addition to the previous findings of albumin and low specific gravity. He was seen in consultation with the Genito-Urinary Service at this time and they felt that his difficulties were due to prostatic obstruction. Following their usual genito-urinary work-up, including pyelography and cystoscopy, a transurethral resection was done. He had a fairly stormy course following this. He bled rather profusely and many clots formed in the bladder. Cystoscopy was done and the clots were removed. They had to resort to suprapubic cystotomy to get the remainder of the clots.

In February, 1942, the suprapubic wound closed and he could urinate well. He was again transferred to the rest home for further convalescence. He apparently got along quite well for about a month. Early in March, 1942, he became decompensated again. There was a three plus edema of the legs. The liver was enlarged. The patient was slightly dyspneic. His blood pressure was 248/136. He was placed on limited fluids in addition to his digitalis and given diuretics. He improved somewhat. The edema went down and he was apparently coming along well. On March 12, 1942, at 4:00 p.m., previously having had a good day, he suddenly became quite cyanotic and dyspneic. He lost consciousness and his pulse became weak and thready. The respirations were fast and labored and then slow and labored. He sank into a coma and failed to respond. He expired about one hour and fifteen minutes after the onset of the attack.

DR. F. ANDRUS: Here we have a man of forty-nine years who had a history of hypertension and rheumatic fever and who had been hospitalized for a period of nine months with severe heart failure which responded to bed rest, digitalis, and to the usual treatment for heart disease with congestive heart failure. Then we notice that when he was compensated, we have a sudden death. Now what things may we think of as the cause of sudden death in this type of case?

DR. A. PEPPARD: I do not want to tell you the cause of his sudden death, but I do want to state that I would object most strenuously to an attempt to make a diagnosis from the information at hand. Even if the autopsy should show that it was due to coronary insufficiency or throm-

bosis, I would still object. There is too much tendency for people to ascribe sudden, unexplained deaths to coronary disease.

DR. ANDRUS: I think that is a good point. If we have a sudden death in a patient having hypertension, too many people assume that the death was due to coronary artery disease without proper and adequate study to support such an assumption. One must remember that in chronic heart failure, pulmonary embolism is very common and is often the cause of sudden death.

Autopsy Findings

DR. RALPH PAPERMASTER: The body was that of a well developed and well nourished white male. There was one plus edema of the legs. Upon opening the abdomen, the peritoneal cavity was found to contain about 100 c.c. of fluid. The pericardial sac contained about 200 c.c. of clotted blood. The tissue at the base of the heart was markedly hemorrhagic. The transverse thoracic diameter was 30 cm. and the transverse cardiac diameter was 20 cm. The heart weighed 980 grams, including the arch of the aorta. All of the chambers of the heart were markedly dilated. The left ventricular wall measured 22 mm. in thickness. The edges of the mitral valve were thickened and retracted. The hemorrhagic tissue at the base of the heart extended 12 cm. up over the arch of the aorta to the origin of the left subclavian artery. The hemorrhage extended up the innominate artery as far as it could be followed. It also extended up the pulmonary artery and into the hilus of the lung. There was some hemorrhage following the anterior descending branch of the left coronary artery for a distance of about 3 cm. but not encroaching upon the lumen of the vessel. Upon opening the aorta, marked atherosclerosis was seen. There was a transverse rent in the intima of the wall of the aorta about 3 cm. above the aortic ring 2 cm. in length. The right end of the rupture was at the orifice of the right coronary artery. Extending distally from the center of the transverse tear was a longitudinal tear 12 mm. long. The rupture appeared to extend through the wall to the adventitial layer of the aorta. The hemorrhage could be followed along the coronary artery, up the aorta and innominate and pulmonary arteries. The lungs were otherwise negative.

The liver weighed 2,400 grams. The surface

was roughened and on cut section the nutmeg was seen. The kidneys each weighed 160 grams. appearance of severe chronic passive congestion. They were pale and had a granular appearance on cut section. The cortex could not be sharply distinguished from the medulla.

Examination of the brain revealed marked arteriosclerosis of the vessels. The cut surfaces of the brain were normal except for two small areas. One area showed encephalomalacia 1 cm. in diameter just above the posterior cornu of the right ventricle. Just below the cortex in the depths of the calcarine fissure on the right there is a thrombosed vessel measuring 2 mm. in diameter.

Anatomic Diagnoses: (1) Hypertension; (2) myocardial hypertrophy; (3) dissecting aneurysm of the aorta; (4) hemopericardium; (5) renal arteriosclerosis; (6) cerebral arteriosclerosis.

Discussion

DR. ANDRUS: In the microscopic examination of the aorta one sees the primary anatomic change encountered in cases of dissecting aneurysm. The change is that of medio-necrosis. The elastic fibers have become frayed and split and broken to give the wall a hyalin or granular appearance. The lesion does not appear to be inflammatory in any sense. It is not related to syphilis although syphilitic aneurysms do occasionally dissect. The lesion is also not related to atherosclerosis which is primarily an intimal change. This medio-necrosis appears to be a change produced by the aging process and it seems to be more marked in individuals who have had chronic hypertension. A very rare occurrence in this case was the dissection out into the

pulmonary artery. The microscopic sections show that the dissection has extended out even to the finer branches. The pulmonary arteries do not show any medio-necrosis. The split in the aorta is between the medial two-thirds and the outer one-third of the blood vessel. Sections of the myocardium show marked hypertrophy of the muscle fibers, and the kidney shows the subintimal deposits of hyalin in the glomerular arterioles which is so characteristic of chronic hypertension. The kidney parenchyma itself appears to be functionally competent.

Dissecting aneurysm is not rare. There are several things that we might learn from this case. In the first place, it is primarily a disease of the media of the great conducting arteries. There is no inflammatory lesion and it is primarily not due to atherosclerosis. In fact, the tear in the intima is in most instances apart from an ulcer. A number of cases occur with some excitement which apparently elevates the patient's blood pressure. I remember doing an autopsy on a woman whose attack developed while she was attending an exciting gangster movie. Severe exertion apparently initiates some of the attacks. Occasionally, the aorta ruptures completely and this patient dies suddenly of what we speak of as spontaneous rupture of the aorta. The symptoms vary tremendously depending upon the course that the dissection takes. Most commonly there is hemorrhage into the pericardial sac so that the ventricles cannot fill during diastole and the patient dies after a short period of coma. Occasionally very unexpected symptoms occur. I remember examining one patient who was seized with a severe pain in his abdomen while walking to work. A few hours later he developed abdominal distension with pain. A diagnosis of intestinal obstruction was made. He died of a mesenteric infarction not due to embolism or to thrombosis but due to the extension of a dissecting aneurysm about the mouth of the superior mesenteric artery so that it was occluded. Another patient presented the complaint of severe pain in the back and anuria. In this case the dissecting aneurysm had occluded both renal arteries causing infarction of both kidneys. Occasionally, the aneurysm ruptures back into the lumen of the aorta and the patient may survive for some time with what we speak of as a healed dissecting aneurysm. It is very interesting to note that the new false passage becomes lined by endothelium and it may become the seat of atherosclerotic patches.

CASE REPORTS

PRIMARY MALIGNANT MELANOMA OF THE CHOROID

H. D. HARLOWE, M.D.
Virginia, Minnesota

MELANOMA of the choroid, a highly malignant type of growth, is comparatively rare. Statistics from large eye clinics reveal an average of only one such instance among 2,000 patients. As a result, it is difficult to obtain a large series of cases for detailed study. However, at Washington, D. C., in the American Registry of Ophthalmic Pathology, there are 1,600 cases of malignant intraocular melanoma. Colonels Callender and Ash³ followed five hundred of these patients

for five years or longer, and as a result made some very interesting observations.

Case Report

The patient, a white male, aged 58, was first seen at home on August 14, 1941. Following a light supper he was suddenly seized with severe abdominal pain, associated with nausea and vomiting. He was found writhing in pain and perspiring profusely and he was immediately transferred to the hospital.

Past Medical History—Patient had had recurrent attacks of tonsillitis over a period of years; chronic

From the Lenont-Peterson Clinic, Virginia, Minnesota.

prostatitis in 1938; and fracture of the first metacarpal of the right foot in 1938. An injury to the right eye in 1926, while employed as a sawyer at a lumber mill, had been apparently followed by complete recovery at the time, but ten years later, presumably the effects of the same injury necessitated the enucleation of the right eye. A tonsillectomy was performed in 1939. During the six months prior to admission to the hospital, the patient had had vague abdominal symptoms, a moderate secondary anemia and a slight loss of weight. A diagnosis of malignancy of the stomach was considered, but roentgenograms and laboratory findings would not substantiate it.

Physical Examination.—The patient, a rather emaciated male, was evidently in severe pain. The right eye was artificial; the left eye had an uncorrected vision of 20/25. The nose and ears were normal. The tonsils had been removed, and upper and lower dentures were present. The heart and lungs were normal. The entire abdomen was extremely rigid without any areas of localized tenderness. There were no palpable masses. A roentgenogram of the abdomen and chest was taken, but showed no evidence of subdiaphragmatic air.

Laboratory Findings.—Hemoglobin, 74 per cent; red blood cells, 3,940,000; white blood cells, 8,350. The differential blood count revealed 87 per cent polymorphonuclears, 10 per cent lymphocytes, 2.5 per cent monocytes, and 0.5 per cent eosinophils. Wassermann and Mantoux tests and the urinalysis were all negative.

Treatment and Course.—A tentative diagnosis of perforated gastric ulcer was made and a laparotomy advised. Upon opening the abdomen a small amount of clear fluid was encountered, and there were small masses of gelatinous material floating free in the abdominal cavity, suggestive in appearance of partially organized old bloodclots. The liver was enlarged and extended about three fingers below the costal margin. It was thickly studded with nodules of a coal black color, varying in diameter from 2 to 3 mm. or 2 or more cm. Careful exploration failed to demonstrate any perforation of the viscus or other pathological changes besides those noted. A nodule was removed from the liver for biopsy. Postoperative inspection of the skin revealed no moles or scars suggesting previous removal of moles. Although the postoperative course was rather stormy, the patient was discharged on the eighth day with the abdominal wound well healed. In the five months that have elapsed since the operation, the man has shown a gradual, yet very marked, decline.

In a discussion of the findings of the exploratory operation with the patient's wife, it was learned that the right eye had been removed because of a malignancy. The attending ophthalmologist in 1936 stated that the patient gave a history of a severe injury, ten years previously, to the right eye. At that time there was facial swelling, but impairment of vision did not occur until about nine years later. Examination showed a severely inflamed right eye with a shallow anterior chamber and a fixed pupil. There was increased tension, a ground glass cornea, and detachment of both retina and choroid. Transillumination of the eyeball was poor, indicating some obstructive substance within the posterior chamber. Diagnosed as sarcoma of the choroid, the eye was enucleated. The malignancy was confirmed by the pathological findings.

The biopsy report of the nodule taken from the liver during exploratory operation in 1941 was as follows: "The black masses are formed by tumor tissue. Some tumor cells have the appearance of epithelial cells while others are elongated and spindle-shaped. The tumor cells have pale-staining, round or oval nuclei, and they are often loaded with a large amount of granular dark brownish pigment. Only few mitoses can be seen. The tumor tissue shows a marked tendency to infiltrate the surrounding liver substance. The diagnosis is metastases of a malignant melanoma to the liver."

Comment

Similar instances of primary intraocular melanosarcoma with metastases have been reported by Dejean,⁶ Kreibitz,⁷ Lacroix,⁸ Acki,¹ Fiessinger,⁶ and others. Burch,² commenting on this case, stated: "In my experience I have seen this happen a number of times. Two years ago, I saw in a ward of a local hospital, a former patient from whom I had removed the eye for sarcoma five years previously. She had just had an exploratory laparotomy. The abdomen was closed without further operation after a malignancy of the liver was discovered. One of my cases developed a metastasis in the thyroid; another developed pneumonia six months after enucleation of the eye, and it was found at autopsy that she had a carcinoma of the lung. It is a common experience after melanosarcoma of the choroid to have metastases develop elsewhere sooner or later, even after a period of eight to ten years. Among some fifty-odd melanosarcomas of the choroid that we have in the University of Minnesota records, together with specimens submitted for examination, we have been trying to send out follow-up letters to ascertain the five- and ten-year cures and the number of metastases that have developed and their location."

Several theories as to the origin of ocular melanoma have been suggested. After making a study of serial sections of seven choroidal sarcomas, Theobald¹⁰ showed that these tumors originate from the Schwann sheath cells of the ciliary nerves as they pass through the choroid. Similarly Masson⁹ observed that all types of sensory and motor neural tumors have as a fundamental element a proliferation of Schwann sheath cells which are ectodermal in origin.

According to their microscopic appearance Callender⁴ classified melanosarcoma:

1. Spindle cell type A and B
2. Epithelioid cell type
3. Fascicular cell type
4. Mixed cell type

The spindle type A has a good prognosis, whereas type B averages a 10 per cent malignancy. In the epithelioid type, the most malignant form of melanosarcoma, approximately 70 per cent of patients expire within ten years. The fascicular type is the next in predominance of metastases; while the mixed cell type has a variable prognosis. According to Callender³ the total number of deaths from metastases, among 500 cases followed five years or longer, was 239, or 48 per cent; the mortality increased to 68 per cent among the 200 cases followed ten years or longer.

Malignant melanoma frequently develops in a blind eye of long standing, as noted in the case reported. Approximately 85 per cent of ocular melanomata are found in the choroid. The possibility of previous injury to the eye as an etiological factor is controversial. Following enucleation for melanosarcoma of the choroid, metastases have occurred even as long as twenty-four years later. Malignant melanoma of the eye is rarely found in children, as evidenced by only thirty-one recorded cases.

As with all malignancies, intraocular melanosarcoma

has a most unfavorable prognosis. Von Hippel¹¹ maintained that enucleation is useless except when done in the very earliest stages of the disease. Therefore, an early diagnosis should be of decided importance in lowering the mortality rate.

Summary and Conclusions

1. A case of primary malignant melanoma of the choroid with metastases is reported.
2. Callender's classification of melanosarcoma is discussed.
3. Attention is called to the variation in time that may elapse between the primary lesion and the development of metastases.
4. An earlier diagnosis of intraocular melanoma is the only way we now have to improve the prognosis.

THE TREATMENT OF THYROID CRISIS With Special Reference to the Possible Use of Spinal Anesthesia

CHARLES E. REA, M.D.
Saint Paul, Minnesota

THE following case is presented because of the improvement noted following the use of spinal anesthesia in a case of severe postoperative thyroid crisis.

The patient was a white, married female, forty years old, who had had symptoms of hyperthyroidism for eight months. She had lost thirty-five pounds in weight in that time, was nervous, irritable, and had noticed a slight exophthalmos. Her appetite was excessive and her palms were always moist with perspiration.

Examination of the thyroid revealed a diffusely enlarged gland. There was slight exophthalmos. Her blood pressure was 140/80. Three basal metabolic rates had been plus 53, plus 32 and plus 20 per cent, while receiving Lugol's solution and sedation for one month. The pulse dropped from 120 to 90 during this time. Examination of the urine was negative. The hemoglobin was 65 per cent with 3,500,000 erythrocytes.

On May 13, 1941, a bilateral subtotal lobectomy was performed. The patient seemed to stand the procedure well, but that evening the pulse rose to 140 per minute, blood pressure 170/90, respiration 32 per minute and temperature 103.6 (rectal). She was restless and somewhat confused mentally. In the ten hour period since operation she had been given 2500 cc. of 5 per cent glucose in normal saline, two doses of morphine sulfate, gr. 1/4, two doses of nembutal, gr. III, 15 gr. of sodium iodide intravenously, 60 minims of Lugol's solution in 200 cc. of tap water by proctoclysis.

When the author saw her in consultation about twelve hours after her operation, there was no question but that she had a thyroid crisis. The attending surgeon had tried everything that is usually given for this condition. It was decided to try to increase the sedation and also to give a blood transfusion. The next morning the patient was very restless and irrational. The nurse said that nembutal, gr. III every two hours for three doses, failed to quiet her. The patient's temperature was 104.6 (rectal), pulse 160 per minute,

blood pressure 180/110, respiration 45 per minute and the patient looked as if she were going to die unless some relief were given shortly. It was then decided to try spinal anesthesia. Sixty milligrams of procaine hydrochloride (novocaine crystals) were given intraspinally in the third lumbar space. Anesthesia was obtained to about the fourth rib anteriorly, but it was not complete, as the patient could still move her legs after the anesthesia was given. The effect on the blood pressure, pulse, respiration and temperature was dramatic. The blood pressure fell almost immediately (shock-like phenomenon?), the pulse and respiration became slower, and the temperature was 100° about three hours later. The patient immediately became quieter and went to sleep. This was somewhat disturbing at first, but since the blood pressure was maintained above shock level, no great concern was felt. The anesthesia wore off in about one and a half hours. Following this, the patient was given phenobarbital, gr. I, t.i.d., and Lugol's solution gt. XV, t.i.d., and 3000 cc. of 5 per cent glucose, half in saline and half in triple distilled water, every twenty-four hours for three days. Twenty-four hours after the anesthesia, the blood pressure and pulse rose temporarily, but this was apparently controlled by nembutal, gr. III. The patient made an uneventful recovery and was discharged on the fourteenth postoperative day. When seen six weeks later, she said she felt better, had gained ten pounds, and was less nervous and irritable. Her basal metabolism rate was plus 12 per cent, pulse 90 per minute.

Discussion

The disturbing feature in the treatment of thyroid crisis or storm is that there is no specific therapy known to date. Fundamentally, the cause of this condition is still obscure. It is not certain whether the primary difficulty lies in the thyroid gland itself or whether other organs, such as the adrenal, liver, pituitary, etc., are the site of the disorder. If the primary organ at fault is the thyroid gland, it is unknown whether

From the Department of Surgery, University of Minnesota Medical School. Read before the Saint Paul Surgical Society, October 9, 1941.

er the symptoms are due to an excess of normal secretion or to an abnormal secretion. Crile seems to believe that the adrenals are at fault in thyroid crisis. Maddock, Collier and Pedersen have found "adrenalin" in the peripheral venous blood of some patients with reactions to hyperthyroidism, the quantities found suggesting a direct relationship to the severity of the reaction. Lahey states that in his opinion "most thyroid deaths are largely liver deaths." The results of the thorough review by Foss, Hunt and McMillan showed that neither the heart, liver, thyroid or thymus alone seemed to be at fault in thyroid crisis. In their opinion there was no proof that thyroid crisis followed sudden hypersecretion of thyroxine, epinephrine or both. Good summaries of the present concepts of thyroid crises are given by Foss, Hunt and McMillan and also Pemberton. One reason why postoperative crisis, in association with typical exophthalmic goiter is now uncommon, is that these patients' are given careful preoperative care. The importance of mental and physical rest, by environment and drugs, high caloric intake and the judicious use of iodine, chiefly in the form of Lugol's solution, is well recognized.

Concerning the operation for hyperthyroidism, there is no question that in selected cases stage procedures have lessened the incidence of postoperative reactions. It is interesting to note how in recent years stage procedures have passed from those of necessity to those of election. Postoperatively, it is important to watch the blood pressure, pulse, respiration and temperature, because if they begin to rise, one should suspect a thyroid storm or crisis. When a thyroid crisis begins or seems imminent, the therapy consists of the judicious administration of sedation; iodine medication by vein, mouth or rectum; oxygen therapy, intravenous glucose and fluid; cold compresses; etc. Occasionally blood transfusions have been given. It would be interesting to see what effect transfusions of blood from patients with myxedema would have on patients with a thyroid storm.

Occasionally, however, in spite of the above measures, the patient does not improve. In such instances, the use of spinal anesthesia might be considered. Crile has reported beneficial results following spinal anesthesia in a few cases of thyroid crisis. Bartels, Stuart and Johnson tried it in one case. While the immediate clinical improvement was striking, the patient subsequently died.* The procedure is not irrational, on the basis that spinal anesthesia temporarily denervates the adrenal glands.

It is not the purpose of this paper to recommend the use of spinal anesthesia in the routine treatment of thyroid crisis. In fact, there are several objections that might be voiced against its use: (1) Spinal anesthesia is not a harmless form of therapy in itself and its use in an ill patient is not without danger, (2) there is no definite proof that the adrenal glands are primarily at fault in thyroid crisis; (3) the *post hoc, ergo propter hoc* type of reasoning is dangerous, especially when other medications were used; and (4) thyroid crisis may cure itself spontaneously.

On the other hand, the whole treatment of thyroid crisis is symptomatic and until a specific cause and treatment for the condition is known, the therapy will be rather empirical. It would seem justified to use spinal anesthesia in selected cases when the usual methods of treatment of severe thyroid crisis have failed. Until more cases reporting the use of spinal anesthesia in thyroid crisis are available, enthusiasm or wholesale application of this procedure is not warranted.

Summary

A case of severe thyroid crisis following bilateral thyroid lobectomy successfully treated by spinal anesthesia is reported. Some general ideas regarding the cause and treatment of thyroid crisis have been discussed. A plea for conservatism in the use of spinal anesthesia in thyroid crisis is made.

SCIENTISTS URGED TO SAVE VALUABLE JOURNALS

Scientists feeling the patriotic urge to turn over to waste-paper collectors piles of old technical journals which they no longer need are urged to look them over first with an eye to their possible use in rebuilding war-damaged libraries abroad. Many such libraries have lost all or part of their files of scientific periodicals, or have been unable to keep them complete due to interruption of the mails or loss of shipments at sea.

The American Library Association has appointed a special committee which is functioning under the chairmanship of John R. Russell, librarian of the University of Rochester, N. Y. Scientists who have accumulations of old journals are requested to write to Mr. Russell, before turning them over to waste-paper drives.—*Science News Letter*, April 25, 1942.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF THE MINNESOTA STATE MEDICAL SOCIETY

By ARTHUR S. HAMILTON, M.D.

Minneapolis, Minnesota

(Continued from April issue.)

Sixth Annual Meeting

The sixth annual meeting of the Minnesota State Medical Society was held in the Grand Army Hall, Saint Paul, on February 3 and 4, 1874, with Dr. W. W. Sweney presiding and forty-five members present.

In his opening address, Dr. Sweney referred to the death of Drs. Noyes, Smith, Chance, Jones, Etheridge, Bingham, Willey and Reiner, and urged that the Society take steps to recommend the establishment of a National Department of Public Health. He also urged the Society to take final action on the rights of women to become members.

Dr. T. T. Mann requested that the Committee on the Influence which the External Aspects of Nature Exercise upon the Imagination and Understanding of Man be continued another year, and this was granted.

No official mention is made of the omission of the semi-annual meeting of 1874, but since previous to the adjournment of the meeting of February 3, 1874, the Society moved to adjourn until the first Tuesday in February, 1875, it must be assumed that the semi-annual meeting was omitted intentionally.

Seventh Annual Meeting

The seventh annual meeting of the Minnesota State Medical Society was held in the Supreme Court Room, Saint Paul, on February 2 and 3, 1875, with Dr. N. B. Hill in the chair, and forty-five members present.

Dr. Hill referred to the death of Drs. Potts, Richardson, Grant and Ames, and gave the following extract from a Minneapolis paper, printed at the time of Dr. Ames' death: "Dr. Ames was one of the most upright citizens that ever lived. He was one of the most temperate and correct men in all his personal habits. He was methodical in the extreme, jotting down in his private diary the principal events of his own life, and those of the city and state around him."

Dr. Hill also referred to the improvement in the state law dealing with post-mortem examinations, and the question of recognizing the right of women to membership in the State Society.

On account of the serious illness of Dr. Hill, which came in the form of a stroke of apoplexy on the morning of the meeting, the vice president, Dr. A. B. Stuart, became presiding officer.

The Committee on New Members submitted a list of applicants for admission, divided into two groups: those presenting diplomas, and those without. Those of one group, as having presented diplomas, were elected to membership.

Later in the meeting, eight additional new members were elected. It is not stated whether these men presented diplomas, but certain things in the context

suggest that they did not. Some are reported as graduates of a medical school and some are not.

Dr. Reynolds of Fergus Falls made application for membership, but this was not acted upon on the ground that his diploma was not presented, and no one was present who had any personal knowledge of him.

Amendments to the Constitution and By-Laws were adopted as seen in another chapter.

On motion, Dr. C. N. Hewitt was called upon to read the annual address of the president, Dr. N. B. Hill. Before reading the address, Dr. Hewitt explained that when he had been in Minneapolis a week previously, he had taken tea with Dr. Hill, who had then shown him the address, and had stated he was anxious to have it received by the Society, as he thought it would be the last effort of this kind he would ever make. Consequently, when Dr. Hewitt saw the manuscript in Dr. Hill's pocket at the time of his stroke, he had taken it out and ventured to present it to the Society.

Dr. Hill's closing address appears in the Transactions for 1875, and is a notable paper, calling attention to many practical points in the practice of our profession, and urging physicians to a higher moral and professional plane of living. He recommended the continuance of the registration of all the regular practitioners in the state, as the only means the public has of distinguishing between the properly qualified practitioners and the mere pretender. Attention was called to the unsatisfactory situation existing in medico-legal matters (unfortunately still existing), and the appointment of an impartial committee of three was urged to pass on all matters of expert testimony. The relation of physicians to public health problems, and the importance of prevention as against cure in the matter of disease was stressed.

At this meeting, the Committee on the Influence which the External Aspects of Nature Exercise upon the Imagination and Understanding of Man, was discharged without report, and we are forever denied what might have been an interesting contribution to medicine.

The Transactions for 1875 contain a copy of the amended Constitution and By-Laws of the Minnesota State Medical Society and also the Code of Ethics of the American Medical Association.

Eighth Annual Meeting

The eighth annual meeting of the Minnesota State Medical Society was held in the Supreme Court Room, Saint Paul, February 1 and 2, 1876, under the presidency of Dr. J. H. Stewart, Dr. N. B. Hill having died with a stroke of apoplexy the preceding February. Sixty members were in attendance.

Dr. Stewart's address on "Professional Etiquette" was well received, and contained many wise admonitions and some highly moral suggestions, couched in rather flowery and sometimes witty language, as to the doctor's behavior.

The date of the annual meeting was changed from the first Tuesday in February to the third Tuesday in June.

The report of the Committee on Surgery contains three carefully studied and well-reported cases by Dr. Franklin Staples on "Plastic Operation of the Lower Lip"; "Fibroid Tumor of the Ischio-rectal Fossa," and "A Large Adenoid Tumor of the Neck."

In the report of the Committee on Obstetrics appear some notes by Dr. H. H. McMahon on "Obstetrical Observations Among the Chippewa Indians of Minnesota." At the time the notes were written, Dr. McMahon had been in active practice for one year and most of his practice was among the Chippewas, but

in that period he had not attended a single case of obstetrics among the Indians as, by their custom, male help is totally proscribed in such cases. During a residence of two years among the Indians he had not heard of a single case of difficult labor, but he had seen one case of puerperal mania. When seen, the woman was tied with a rope around her waist and was "raging wildly about the wigwam as far as the rope would permit." She had no medical treatment but ultimately fully recovered.

In one case of miscarriage, the doctor saw his patient about two hours afterward, and she was then on her knees in the wigwam washing the clothes. It was customary among the women to get up immediately after the child was born and go to work, or, if delivery occurred while on the march, as soon as it was over the mother picked up her pack and proceeded on her journey. Nevertheless, uterine disease of any kind was extremely rare among the Indians, and the doctor knew of no instance of prolapse of the uterus.

The old women usually attended the cases of childbirth, and went prepared with roots and herbs of some kind which they administered with a view of promoting uterine contractions. They had no knowledge of turning the child but Dr. McMahon had heard that there were cases where they dissected the fetus *in utero*, with no other instrument than the common scalping knife.

The Committee on Obstetrics also reported on the use of forceps as a means of compression of the fetal head as well as for traction purposes.

It is worthy of note that many of the reports on special subjects in medicine and surgery are given in much detail, refer at length to new procedures and serve much the same purpose as our present-day annual reviews on different aspects of medicine.

The Committee on Gynæcology reported three successful ovariectomies in Minnesota during the preceding year.

As chairman of the Committee on Necrology, Dr. O. J. Evans of Minneapolis reported on the death of Dr. N. B. Hill, the only death of the year.

Dr. Milligan and Dr. T. H. Evarts moved that the Minnesota State Medical Society urge upon the Legislature the necessity for the immediate organization of an inebriate asylum, it having come to their attention that the state senate had voted the disestablishment of the Minnesota State Inebriate Asylum established the preceding winter, and the House was strongly urged to nonconcur in the action of the Senate.

The delegates elected to the International Medical Congress to be held at the Centennial Exposition in Philadelphia were: Dr. A. B. Stuart from the First Congressional District; Dr. C. N. Hewitt, from the Second Congressional District; Dr. C. E. Smith, from the Third Congressional District.

Frequent reference is made in medical articles of this period to laudable pus, and there is also considerable discussion on the diagnosis of typhilitis and perityphilitis.

Ninth Annual Meeting

The ninth annual meeting of the Minnesota State Medical Society was held in the Senate Chamber at Saint Paul on June 19 and 20, 1877. Dr. F. H. Milligan presided and sixty-four members were present. Dr. Milligan urged compulsory vaccination; a committee to examine all persons desiring to become druggists or apothecaries, and that suitable provision be made by the United States for the families of the discoverers of anesthesia.

Dr. Milligan's presidential address was entitled "What Has the Science of Medicine and Surgery Done to Benefit Mankind?"

Dr. Staples presented a paper on carcinomatous infections and illustrated it with crayon sketches, photographs and pathological specimens. It is noteworthy that Dr. Staples' prize essay in a previous contribution was illustrated by drawings, the first of which I have found any record in the Society.

Dr. Hewitt urged the Society to aid in practical temperance reform, and asked that a committee of three be appointed whose duty it should be to collect facts bearing upon the use and abuse of alcohol in the state, to report next year and, if possible, to suggest a remedy. Drs. Dodge, Hewitt and Craft were appointed.

Tenth Annual Meeting

The tenth annual meeting of the Minnesota State Medical Society was held at St. Peter on Tuesday and Wednesday, June 18 and 19, 1878. Dr. Otis Ayer presided.

An unusually large number of new members were admitted.

Dr. Adams announced that Dr. J. H. Murphy had been elected as one of the vice presidents of the American Medical Association.

Reference was made to a resolution passed the preceding year on the subject of "Shortening in Fractures of the Long Bones," and to a paper on "Congenital Irregularities in the Length of the Lower Limbs." A committee consisting of Drs. J. H. Murphy, E. J. Davis, S. Blood, J. E. Bowers and S. B. Sheardown was appointed to collect statistics on the congenital difference in the length of lower limbs. Obviously, all this suggested unusual activity in malpractice suits.

A resolution passed by the Society earnestly urged the legislative assembly of the state to so amend existing laws as to require medical experts to hear fully the evidence on both sides of the suit before expressing an opinion, in the several courts of justice of this state.

Under the heading of "Reports on Surgery," Dr. A. B. Stuart of Santa Barbara, California, formerly of Winona, made some comment on the climate of California in relation to injuries and disease. It was his opinion that recent incised and lacerated wounds acted more kindly and healed more rapidly on the Pacific Coast than on the Atlantic Coast or in the Valley of the Mississippi. Broken bones, on the other hand, did not unite more rapidly than in the eastern states, and this disagreement in the healing power of the two tissues was referred to, but was accepted as beyond explanation, except that ozone, which Dr. Stuart calls vitalized oxygen, was considered more abundant on the Pacific than on the Atlantic Coast.

On Wednesday afternoon and after the final adjournment of the Society, its members were afforded an opportunity, through the kindness of Drs. Bartlett, Bowers and James of the Hospital for the Insane, of visiting that institution. Most of the Society had never previously visited the hospital. There was general approval of the admirable arrangement of the hospital, its surprising extent, and its excellent administration.

(To be continued in the June issue)

President's Letter

SICKNESS INSURANCE—THE MAY DAY PROCLAMATIONS

I

THE members of the State Association can be assured that even in this time of stress the question of sickness insurance is receiving careful consideration. Our Committee on Sickness Insurance under the chairmanship of Dr. A. W. Adson has been active. Certain members of the Committee attended the Conference on Medical Service Plans in Chicago last February; a report of this conference can be found in the April issue of MINNESOTA MEDICINE, page 290. Since then the Committee has formulated a program of study for the situation in Minnesota.

In general, there are four types of medical service plans: (1) the cash indemnification plan, which is chiefly exemplified by policies written by the commercial insurance companies in which claims are paid directly to the client; (2) the group clinic plan, and the consumers' group health plan in which different types of medical service are given directly to the patient for a certain fee per month; (3) the voluntary prepaid medical service plan sponsored by medical societies, and (4) the compulsory prepaid medical service which would be controlled by the state or federal government. It is estimated that about 6 per cent of the population of the United States, or approximately 7,000,000 persons, subscribes to sickness and accident insurance of the cash indemnity type. About 150,000 persons are served by means of group clinic and consumer plans, and 750,000 persons by voluntary prepaid medical service plans. Additional material on the various plans is being assembled for the meeting of the American Medical Association in June, at which time the permanent organization of prepaid medical service plans will be given consideration.

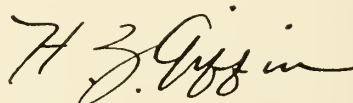

The Committee on Sickness Insurance of our State Association has appointed two subcommittees: one, to study the question in the urban areas and the other in the rural areas. It is felt that the problem may be different in these two areas. A subcommittee also was appointed to make a study of enabling acts which are now in force in various states and to consider the preparation of an act which might be suitable for Minnesota. The results of the studies of these subcommittees will be available at the time of the annual meeting in Duluth, and members of the House of Delegates should be prepared to enter into a discussion on this question.

Medical service plans of the type under consideration have nothing to do with the care of indigents. Subscribers to plans of this type can be only those who can afford to buy the service. Care of indigents is an independent topic. The most important questions to be decided concerning medical service plans are whether or not an enabling act should be sponsored, whether some service plan on a state-wide basis is advisable, and whether a satisfactory plan for this service can be found. The effects of such plans on the quality of medical care, the advancement of medical science and medical art, and the physician-patient relationship are larger aspects of the problem. Innumerable details must be considered; for example, x-ray and laboratory services, pediatric, obstetric and psychiatric care, refraction, the services of the specialist, and actuarial bases for estimating insurability. A conception of these can be obtained from the publications of the American Medical Association and The Actuarial Society of America.

II

The May Day proclamations of President Roosevelt and Governor Stassen on vaccination and immunization were a great help to physicians and public health officers. The campaign for vaccination and immunization in Minnesota has been, of course, a continuous campaign for these many years. It was recognized two years ago by the Council of the Minnesota State Medical Association that more active measures would be necessary, and since that time much has been accomplished through the activities of Dr. L. R. Critchfield and his Committee on Vaccination and Immunization. In spite of exceptional accomplishments at this time, the campaign will carry over into the summer and become again a continuous campaign on the part of the State Board of Health, the State Medical Association, and all the lay organizations affiliated in this work.

The necessity for vaccination of adults should be emphasized. Many adults have not been vaccinated for twenty-five years, whereas vaccination every six or seven years should be recommended. Adults hesitate to be vaccinated because of their favorable past experience. They do not realize that if we should have an epidemic of malignant smallpox as we had eighteen years ago, undoubtedly many of them would be susceptible.

CHEMOTHERAPY AND TUBERCULOSIS

THE progress made in recent years in the
elaboration of chemicals which have a specific
effect on pathogenic organisms constitutes, not
simply a milestone in medicine, but it is to be
hoped, the beginning of an epoch in the history
of therapeutics.

It is only through further research that new
chemicals can be discovered which will be more
effective and perhaps less toxic than those now
used clinically in the treatment of a number of
infections. Only by this means (our anti-vivisection
friends, please note) can new chemicals be

elaborated with specific therapeutic value in additional
infections.

Although the mortality in tuberculosis has been
agreeably reduced during the past twenty-five
years, the infection still is an important enemy
of man. The progress in combating the disease
has been made largely through sanatorium care
and segregation, building up nature's resistance
and the various newer operative procedures.

It would seem that the dream that some chemical
could be discovered which would have a
specific deleterious action on the tubercle bacillus,
in spite of its inaccessible location in the tubercle
is not beyond the realm of possibilities.

The paper entitled "Chemotherapy in Experimental
Tuberculosis" by William H. Feldman of
the Division of Experimental Medicine of the
Mayo Foundation, which appears in this issue of
the journal, reports the definite beneficial effects
of a new chemical called promin on induced
tuberculosis in guinea pigs. The next step will
be its clinical trial. The evidence of its value
experimentally is so striking that we welcome
the opportunity of presenting the report to our
readers.

Dr. Feldman was assistant professor of pathology
for ten years at the Colorado State College
before he joined the staff of investigators at the
Institute of Experimental Medicine of the Mayo
Foundation. The report constitutes an address
given under the John W. Bell Tuberculosis Lectureship
before the Hennepin County Medical
Society in February. The lectureship was established
in May, 1930, by the society in memory of
Dr. John W. Bell, a prominent internist of Minneapolis,
who died in 1933 after practicing in that city for
fifty-one years. The lectureship constitutes a continuation
of the fight against tuberculosis in which he was a
pioneer as a founder of the Hennepin County Tuberculosis
Association.

SISTER KENNY

SISTER KENNY has made a valuable contribution
to the treatment of poliomyelitis. After a thorough
trial of her method at General Hospital in Minneapolis
this is the conclusion

of the orthopedists who have observed the results.

During her work as a trained nurse in the bush country of Australia, Sister Kenny encountered a few children suffering from acute poliomyelitis. Not knowing the orthodox medical treatment of the acute disease, she made the observation that there was muscle spasm, tenderness and increased irritability in the unaffected muscles. She discovered that this could be overcome by the use of hot moist applications. The spasm relieved, deformities were less likely to occur and the paralyzed muscles, as they resumed at least a part of their function, were enabled to act with less interference.

Upon regaining medical contact, Sister Kenny immediately realized that her results were far better than those attained by the orthodox method of splinting for six weeks, and then more splinting. With pertinacity born of conviction she tried to convince the profession of the value of her discovery. She made little or no progress in her own country (a prophet is not without honor save in his own country) and it was not until she was given the opportunity to demonstrate her method in Minneapolis that she made any headway. It is said that medicos who come to scoff leave convinced.

Sister Kenny's treatment further includes the training of affected muscles. She speaks of mental alienation which, although difficult to explain, means the absence of voluntary muscle response due to the experience of pain in previously attempting such movement. Patient, passive and active muscle movement with retraining of muscle action within the ability of the disabled muscles, and coördination of muscle action are among the ends sought.

Sister Kenny's treatment is not a cure-all. It does not restore destroyed anterior horn cells. It does afford the individual a chance to use what muscles are able to function by preventing contractures. Braces and supports will still be needed in certain cases. Even orthopedic surgical procedures will still be needed in some cases. But that there will be less need for such treatment is the conviction of those who have observed the results of Sister Kenny's method.

Training courses for physicians, nurses and physical therapy technicians are being instituted so that wider use of this method will be possible.

WAR SESSIONS OF THE AMERICAN COLLEGE OF SURGEONS

LAST January the Regents of the American College of Surgeons voted to institute a series of twenty-five one-day sessions in different localities throughout the country for the benefit of the medical profession, these sessions to be devoted to the consideration of medicine and surgery in military service and civilian defense. Every state will be provided for, either singly or in combination.

On Friday, May 1, a meeting of the profession of the states of North Dakota, South Dakota and Minnesota was held at the Radisson Hotel in Minneapolis.

The program included the latest and most authentic information on war medicine and surgery, including such subjects as shock, the treatment of open wounds, burns and fractures.

Besides local surgeons, Dr. A. W. Adson of Rochester, Minnesota, spoke on "War Injuries of the Face and Skull." Fractures was the subject of Dr. Paul B. Magnuson of Northwestern University Medical School. Representatives of the Medical Department of the Army and Navy spoke on the organization and functions of their respective departments. Dr. Wallace Hunt of Omaha presented information on the doctor and hospital in civilian defense. The Procurement and Assignment Service was presented by Dean Diehl of Minneapolis.

These valuable meetings are being held for the benefit of the profession at large and some of the addresses will appear at an early date in MINNESOTA MEDICINE.

AMERICAN COLLEGE OF PHYSICIANS' MEETING

THE annual meeting of the American College of Physicians, held in Saint Paul last month, was well attended considering the fact that our country is at war. Some 1,377 physicians registered. The program reflected the present trend of medical interest and the effect of war on medical thought was evident. With nearly a dozen clinics taking place simultaneously each morning, and half as many panel discussions occupying each noon hour, a five-ring circus would have been infinitely easier to follow.

With the world as a battleground, the profession has suddenly become conscious of the inadequacy of medical training in this country in

tropical medicine. Already our young men are in the tropics and thousands more will follow them. They will encounter diseases against which white men have poor resistance. Medical officers will be confronted with problems of sanitation, vital for the preservation of the health of our soldiers.

Vaccination against smallpox, typhoid and tetanus is routine. For troops designated for certain disease infested areas, additional vaccination will be provided. But for such diseases as malaria, amebic and bacillary dysentery, cholera, typhus and plague, sanitary methods must be relied upon, if our fighting units are to be kept fit. The experience of our forces on the Bataan Peninsula has demonstrated what tropical disease can do to troops. And after the war the scene is set, even in Minnesota, with the known presence of the anopheles mosquito in our river valleys for the spread of malaria of virulent type from returned infected soldiers. There is a great need of concentration on the subject of tropical disease in our medical schools, as well as among physicians in army and civilian practice.

Aviation medicine was touched upon at the meeting of the College. Many were disappointed that the war prevented Captain Poppen and Major Armstrong from attending and presenting their addresses on this subject. More has to be learned concerning the effect of sudden changes in atmospheric pressure, oxygen tension and speed on human physiology.

Recent work on poliomyelitis was presented, which tends to show that this disease may be an alimentary rather than a respiratory infection. Doctors Paul and Trask of the Yale University School of Medicine presented the results of their investigations, for which they received the John Phillips Memorial Medal awarded by the College.

The endocrines received considerable attention. The whole subject is in the process of development and is somewhat controversial. The practical application of present knowledge derived from animal experimentation is still somewhat limited and the profession was warned against the useless and even dangerous use of some of the preparations.

Geriatrics received considerable attention on the program. The ever-increasing proportion of older people in the population will require an increasing proportion of medical services. Every

man at sixty is not ready physically or mentally to retire. Some have just reached their greatest efficiency with their judgment developed by experience, and while they have lost the elasticity of youth and are not material as airplane pilots, they are most valuable members of society. The routine retirement by industry on a basis of age attainment alone is deplorable.

At the Convocation 302 newly elected Fellows assented to the Fellowship Pledge of the College.

At this session Dr. Roger I. Lee of Boston retired from the presidency and Dr. James E. Paullin of Atlanta took over the leadership. Dr. Ernest E. Irons of Chicago is president-elect. Dr. Charles H. Cocke of Asheville, North Carolina, was elected first vice president; Dr. Henry R. Carstens of Detroit, second vice president, and Dr. A. Comingo Griffith of Kansas City, Missouri, third vice president. Dr. W. D. Stroud and Dr. George Morris Piersol, both of Philadelphia, were reelected treasurer and secretary-general, respectively. The session will be held in Philadelphia in 1943.

BUY WAR BONDS

AMERICA today needs the coöperation of every citizen—the man in uniform, the worker on a production line, the professional man, the woman in the home. Those of us in medicine are well aware of our obligation to the nation. We are willing and eager to provide the best of our professional service to the armed and civilian forces abroad and at home. We will share also the responsibility of providing money for the greatest war machine America has ever known. There must be no fiscal barrier in our war effort.

We are paying higher taxes than ever before, it is true. But increased tax revenues will not meet the annual costs of war. The Government can secure a part of the money from banks and other lending agencies, but extensive borrowing from these sources contributes to inflation. To borrow the money, yet to avoid the inflation threat, the Government asks for loans from all Americans through the purchase of United States Savings Bonds. By investing our money in the nation's war securities we build toward our own future security.

There are registered, interest-bearing bonds for us as individuals and for all medical associations. Series E Bonds are the "People's Bonds" which can be purchased only by individuals. The smallest costs \$18.75 and pays \$25 at the end of ten years—a 33⅓ per cent increase in value. Series F Bonds are also appreciation bonds, but

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics

of the

Minnesota State Medical Association

George Earl, M.D., Chairman

ENROLLMENT FORMS ARRIVE

The long-awaited Medical Enrollment Form from the Procurement and Assignment Service is at last off the government printing presses. It arrived in the offices of Minnesota doctors April 22.

This is the form which is designed to put every doctor in the United States in the service of his country, to be used wherever he will be most valuable.

Each physician who fills it out and returns it to the Executive Officer of the Procurement and Assignment Service will receive a certificate and lapel button to indicate that he is ready to meet his country's need. If he remains at home, it will be because he is needed at home. At the same time he stands ready to serve in any essential civilian activity as well as in the armed forces, if the agency calls him.

The questionnaire and enrollment forms previously returned to the American Medical Association and to the Procurement and Assignment Service are now being utilized to meet requests coming in daily from the armed forces and other agencies. Names selected from these forms are sent to state procurement committees and through them, to local county committees for information on availability.

All Should Fill Them Out

Future needs for both military and civilian services will all be met through the Procurement and Assignment Agency and the new forms will be used in the same fashion. All are requested to fill them out including those who filled out the previous one from which selections are now being made. The additional information, it is pointed out in the letter from Dr. Frank Lahey, president of the American Medical Association, which accompanies the form, will bring up to date the facts necessary to place each medical man in the country in the work for which he is best qualified.

Minnesota's record for returning the first American Medical Association questionnaire was close to the top. Officials are confident that the response to the new questionnaire will be equally prompt and satisfactory.

ATTENDANCE AT MEDICAL MEETINGS

Physicians can be divided into two great groups according to Dr. Henry A. Christian of New York in a message mailed recently to members of the American College of Physicians. These groups comprise those who are learning and those who are forgetting, those who each year know more and those who each year know less. There seems to be no third group, he says, no group that remains stationary.

Dr. Christian's message was sent to stimulate attendance at the Physicians' meeting in St. Paul but applies with equal point to attendance at the 89th Annual Meeting of the Minnesota State Medical Association in Duluth. The state meeting is scheduled for June 29, 30, and July 1 at the Duluth Armory and, as always, it will be one of the most important Northwest medical gatherings of the year. Like the meeting of the College, this also is a chance to increase in knowledge.

"A few physicians increase in knowledge from within and grow from their own doing," Dr. Christian says. "These are innate investigators. The rank and file require outside help to grow and to progress. Books, meetings, discussions, teachers are our armamentarium for progress. Like the spring tonic of past days, all of us need some of this medicine, at least annually, better if it comes more frequently. A large majority of physicians know of their need and seek treatment.

Knowledge Not Static

"Things in nature rarely are static; they increase or they decrease; they grow or they decay;

they progress or they retrogress. Man's education in many respects resembles things of nature; rarely is it static. When knowledge does not increase, almost always it decreases. Physicians should remember this and make every effort to keep out of the static state and on the side of increase of growth, progress.

"Contact with colleagues eager to learn, listening to discussion by those capable of teaching, witnessing demonstrations and clinics, seeing scientific exhibits lead to more reading and better observation of patients. Herein lies medical progress."

The meeting of the Minnesota State Medical Association provides just these opportunities. Attendance at this meeting is a potent way for a physician to get himself out of the group of those who each year know less. The stimulus received from attendance at a medical meeting where men eminent in the profession speak lasts long after the meeting is over.

TROUBLE IN NEW YORK

Physicians who secure for themselves exclusive privileges under special legislation for the organization and operation of prepayment plans for medical service may find themselves in an embarrassing and difficult position if the plans they start are not successful.

The preliminary report recently issued by the Superintendent of Insurance of New York State finds that progress of the non-profit indemnity corporations (controlled and administered by physicians) has been unsatisfactory in New York for example. His department feels, he says, that a modification in the law which permits medical organizations, only, to operate plans for medical service, is needed.

As a result a bill has already been introduced at the 1942 session of the New York State Legislature which would permit hospital corporations to supplement contracts for hospital service by furnishing provision of indemnity against physicians' fees and obstetrical care.

Here, in part, is what the Superintendent of Insurance has to say about the matter:

"Progress Unsatisfactory"

"Although progress made by the hospital service corporations has been satisfactory, that of the non-profit medical indemnity corporations has

been discouraging, particularly in the New York City area. One received a license during 1941 which brought the total of such licensed corporations to five. Three of these are in the metropolitan area, one in Buffalo and one in Utica. Permits to solicit subscribers have been issued to two additional corporations, both of which are located in the metropolitan area. At the end of 1941, the outstanding contracts numbered less than 10,000.

"The Department has recognized from the outset that for many of these plans to be successful they must have substantial support of the medical profession. In Buffalo and Utica the doctors in general have supported the plans and this may account to some extent for the greater progress they have made. In the metropolitan area the Medical Expense Fund of New York, Inc., is the only one to date which has received any substantial backing from the medical profession. Inasmuch as that corporation did not receive its license until August, 1941, sufficient time has not yet elapsed to ascertain how successful it will be.

"Premium is Deterrent"

"The sponsors of the plans have underestimated the time and money that is required in developing and in adequately bringing this type of insurance coverage to the attention of the public. It is now generally understood that these plans will not sell themselves. There are indications that the amount of premium charged is deterrent to the sale. It must be recognized, however, that the doctors to join in a plan must have some reasonable assurance of receiving a reasonable return for their services. To provide coverage at a fee which is attractive to the public on the one hand, and is acceptable to the doctors on the other does offer a real problem. It is undoubtedly true that persons in poor financial circumstances could not afford to pay the subscription fees charged by most of these plans. It is frequently stated by the medical profession that they are willing to treat even free of charge those who are unable to pay, but that they do not feel they should be called upon to furnish for an inadequate amount care to those who can afford to pay. It is to meet this situation in part that one of the plans provides for a graded scale of fees to be paid by the subscribers in accordance

with their income, although the services received would be the same for everyone.

Appeal of Surgical Benefits

"A greater appeal seems to exist for surgical benefits rather than for general medical coverage. This is due perhaps to the possibility of being confronted with much more substantial bills for surgical services than for general medical expense. It is understood that the plans contemplate experimenting to a greater extent in this field. To facilitate the extension of surgical benefits it has been urged that an existing hospital plan which has the minimum surplus of \$150,000 required of newly organized mutual accident and health companies could be given an additional power of including surgical benefits in its subscribers' contracts, such benefits to be graded according to a fixed schedule of surgical operations. This schedule would represent the maximum payments by the plan at any time and the contract would not interfere in the relations between the surgeon and the patient since the contract would be one of indemnity rather than service. Where the charter powers were so enlarged the law might provide for some representation by participating surgeons on the board of directors of the particular hospital plan. The Department feels that a modification of the law granting this additional power would be proper and desirable in order to permit further experimentation as present methods do not seem to be meeting the immediate problem of medical and surgical care for a substantial proportion of the population."

Step Toward Lay Control

Officers of the Medical Expense Fund of New York are rightly disturbed by the situation. They see that passage of the bill now in the legislature, known as the Hampton Bill, would open the way for the practice of medicine by hospitals, with hospital insurance corporations in control of rates, physicians' fees and solicitation of public participation from all economic levels . . . a long step toward lay control of medicine and the end of private practice, they declare.

They see, also, that the position of the Insurance Department is reasonable. They themselves have acknowledged the need by their experiments with prepayment service. They have also taken steps to prevent others from stepping in where they fail.

"If the medical profession does not have a sufficient interest in the promotion of voluntary cash indemnity insurance," they point out in a recent bulletin on the subject, "then the Insurance Department wants to give the hospital plans the opportunity to make a success of it . . . to bring about a satisfactory participation of both the public and the profession.

"... If We Fail"

"Eight months remain," they point out to their physician members, "in which we must promote voluntary non-profit cash indemnity insurance to success comparable with hospital service insurance or the opportunity of control over medical insurance will pass from our hands. The 1943 session of the Legislature will surely pass the Hampton bill if we fail."

The moral in all this is clear. Medical organizations must be sure of their ground and their plan must be as sound as they can make it, before they ask for exclusive privileges from the Legislature. After that they must promote their plans with the utmost vigor. If success is possible, they must be successful because others will be waiting to push their claims and the legislature will not be likely to turn a deaf ear to them if the doctors fail.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Hutchinson Osteopath Pleads Guilty to Abortion

Re: State of Minnesota vs. Solon L. Leonard
On March 30, 1942, Solon L. Leonard, sixty years of age, a duly licensed osteopath of Hutchinson, Minnesota, entered a plea of guilty in the District Court of McLeod County, to an information charging him with the crime of abortion. The defendant was sentenced by the Hon. Joseph J. Moriarty, Judge of the District Court, to a term of not to exceed four years in the State Prison at Stillwater, and was placed on probation. Prior to suspending the sentence, the defendant and his attorney stated to the Court that Leonard would not re-open his office in Hutchinson, would make immediate arrangements to dispose of his home, and would leave the community to live elsewhere.

The defendant was arrested on March 25, 1942, following an investigation by Mr. Frank Broderius, Chief of Police of Hutchinson; Mr. William O. McNelly, County Attorney of McLeod County, and the State Board of Medical Examiners. The defendant had been under suspicion for some time, and in the instant case, had performed a criminal abortion on March 19, 1942, on an eighteen-year-old married girl who resided in Renville County. The defendant admitted to Chief Broderius and a representative of the Minnesota State

THE PREVENTION OF HEAT SICKNESS

HEAT sickness can be prevented by a few simple rules of diet, proper living habits, and the replenishment of salt lost from the body through excessive perspiration. In most cases, the program of prevention of heat sickness ends with the use of sodium chloride tablets, plain or combined with sugar, which are provided to the workers in convenient dispensing containers. This is an essential part in its prophylaxis but the individuals who do their work in abnormally hot or humid environment as well as the entire population exposed to very hot weather must be educated to a twenty-four hour program of prevention of heat sickness.

Diet Important

First consider food. This should consist of an easily digested high carbohydrate, low fat diet with an adequate amount of beverage such as water, fresh fruit juices, milk, carbonated drinks, and possibly tea or coffee. Strong alcoholic drinks should never be used in hot weather. Beer and ale are permissible in small quantities. Frequent small drinks of beverages are safer than a large amount at one time which leaves the individual bloated and frequently causes nausea or vomiting on resumption of work. Ice cold drinks must be sipped slowly. Fried foods, canned or over-ripe corn, canned meats, or heavily spiced foods such as sausage are difficult to digest and predispose the hot weather worker to gastro-intestinal complaints. The large meal should come after returning home from work; a light, easily-digested but nourishing meal before work and at lunch.

Haste Should Be Eliminated

Living habits should provide some recreational facilities such as gardening, reading, fishing, or other light activity but must not encroach on the workman's seven to nine hours of sleep. A cool shower or tub bath before going to work and

repeated on completion of work does much to minimize the effects of a hot job or warm weather. Sufficient time must be allowed for going to work to avoid running or undue excitement in getting there on time. Once on the job the worker should continue to be calm and should use the minimum effort compatible with efficient handling of his work. Avoid unnecessary running. Eliminate all non-productive motions.

Use of Salt

The use of salt tablets should be limited to 10 grains every two hours. Some men will tolerate more than that but the percentage of gastric upsets is high. More than 10 grains every two hours should rarely be necessary in the most extreme heat tolerated by man. The actual salt loss during working hours may exceed this amount but should be supplemented by the regular dietary intake. Added energy is sometimes provided through the addition of invert sugar to the tablet which also increases its palatability. Some individuals who do not tolerate the plain salt well can use the sugar and salt combination or an enteric-coated tablet. In the latter case sufficient time should be allowed from ingestion until the salt is needed by the body to permit the dissolution of the coating and absorption of the salt. Such tablets have been recovered in the stool with only part of the coating dissolved. This should be blamed to the type of coating used.

First Aid for Heat Shock

Men employed at glass or metal furnaces, in rolling mills, open pit mines or in similarly hot environment should be instructed in the recognition of heat shock and heat retention as shown with the use of a thermometer. Through the prompt first aid treatment before medical aid arrives the patient may avoid serious injury.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of March 11, 1942

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, March 11, 1942. Dinner was served at 7 o'clock and the meeting was called to order at 8 o'clock by the Secretary, Dr. Kenefick, both the President and Vice-President being absent.

There were forty-five members and one guest present.

Minutes of the February meeting were read and approved.

The Secretary read a letter of thanks from Dr. Donald McCarthy, expressing his appreciation for the action taken at the January meeting, in which the members voted to make Dr. McCarthy an Active Member without the presentation of a thesis in view of his Navy service.

There being no further business, the scientific program followed.

ECTOPIC PREGNANCY—AN ANALYSIS OF 102 CONSECUTIVE CASES

WILLIAM P. SADLER, M.D.
Minneapolis

Dr. Sadler, of Minneapolis, read his Inaugural Thesis on the above subject. Lantern slides were shown. (Complete paper to be published later).

Abstract

One hundred two proved cases of ectopic pregnancy were admitted to the Minneapolis General Hospital during the nine year period (1932-1940). Incidence in this hospital is one ectopic for every 174 intrauterine pregnancy.

A survey of the literature shows considerable variation in the total and operative mortality rates. The total mortality in 588 cases was 5.4 per cent and the operative mortality rate in 909 cases was 2.93 per cent. In this series we had a total mortality of 2.94 per cent and an operative mortality of 1 per cent. These favorably low rates are especially noteworthy because of the high percentage of cases admitted in shock. The average incidence of shock reported in the literature is 15 per cent. Twenty-eight (27.4 per cent) of our patients were in varying grades of shock, eight of these being practically moribund.

Definite diagnosis of ectopic pregnancy presents many difficulties. In cases collected from the literature, the percentage of correct diagnoses ranged from 37.5 to 47.7 per cent with an average of 64.6 per cent for 915 cases. In this series a correct diagnosis was made in 56.6 per cent of the cases.

One hundred of our patients were white. The age ranged from 18 to 43 years. Sixty-five or 63.7 per cent were in the decade 25 to 34 years. The number of pregnancies ranged from one to eleven. A period of relative sterility from six to seventeen years occurred in 26.6 per cent of our cases.

The duration of pregnancy in this series was 14 weeks or under in all cases except one secondary abdominal pregnancy at 8 months and one intraligamentous pregnancy at 20 weeks. Location was in the right tube 59 times and 42 times in the left. There were three interstitial pregnancies, (2.9 per cent). Intraligamentous pregnancy is rare. Its occurrence in five of our patients is extremely high.

Thirty-two (31.3 per cent) of our patients had undergone 38 previous laparotomies. This finding supports the observation that previous lower abdominal surgery contributes to the incidence of ectopic pregnancy. There was a low incidence of previous pelvic infection, 18.6 per cent confirmed histologically.

Eighty-nine of these patients had undergone 239 previous pregnancies. Of these, 170 delivered at or near term (71.13 per cent). The number of fruitful pregnancies, (71.13 per cent), is approximately that of the general population, (80 per cent). This indicates the fault is not with the fertilized ovum but the site of implantation. Five recurrent ectopics (4.9 per cent) in this series is high.

Abdominal pain was the predominant symptom. It occurred in 97.1 per cent of the patients. Vaginal bleeding was the next most common symptom. It was present in 76 per cent of our cases. Amenorrhea occurred in 70 per cent of the patients, twenty-four patients missed no periods. Shoulder strap pain was elicited in a high per cent (31 per cent). Abdominal distention in 36 cases is much higher than generally reported by others.

Immediate operation as soon as the diagnosis was definite was the usual procedure. Fifty-three patients were operated upon within one hour to less than twenty-four hours after admission. Expectant treatment is not recommended. Removal of the affected tube only was the operation of choice. Forty-five patients received eighty-two transfusions and there were three reactions (3.6 per cent). A reaction rate of the minor variety of 3.6 per cent compared to the generally estimated rate of 5 to 10 per cent shows that ectopics tolerate transfusion well. Reactions due to presence of intragroup agglutinins and anti Rh agglutinins recently emphasized in late pregnancy would seem not to be feared in early ectopic pregnancy.

The rate of blood sedimentation was markedly accelerated in cases with massive hemorrhage. Routine repeat hemoglobin and erythrocyte determinations proved valuable.

Two cases of tubal endometriosis were demonstrated histologically. Abdominal endometriosis in the upper angle of a previous operative scar was observed in one case.

Incorrect diagnoses can be materially lowered by proper interpretation of the history and evaluation of the clinical and laboratory findings.

Discussion

DR. J. C. LITZENBERG, Minneapolis: I suppose after what Dr. Sadler said, I ought to discuss this paper. There is one thing he has spoken about tonight that is worthy of particular significance, and that is their low percentage of proven previous tubal infections. That has been a question of controversy ever since the question of ectopic pregnancy has been discussed. His last remark about Lawson Tait is classical. But, in connection with that, one is impressed with the philosophy of the older clinicians. Everything that Lawson Tait did was reasoned out by a Frenchman—Dr. Donis. He figured out how ectopic pregnancy should be treated and the whole procedure which Lawson Tait afterwards advocated and confirmed was the philosophy of Donis. There is one classical remark by one gynecologist and obstetrician about the cause of ectopic pregnancy being due almost always to infection of the tubes with which he disagreed and closed his discussion by saying the more careful histologic studies are made in these cases the lower is the incidence of infection; most of them will be found not to be due to salpingitis. Dr. Sadler's percentage due to infection was low and proves that point, and also proves the other point that if these cases are examined histologically they will prove not always to be due to salpingitis; though, of course, some of them are.

As to the question of transfusion, I agree with Dr. Sadler, almost completely. I don't think it is a question of transfusion before, between or during operation, but a question of the time the transfusion is given before operation. The patient should not be transfused too soon before operation, else the transfused blood may be lost. The statement that ectopic pregnancy is a hemorrhagic tragedy sums up the whole thing. The patients are in shock from loss of blood and not from surgical shock. The source of that blood loss should be ligated in order to hurry along the recovery.

There are many things that have been controversial, but these few mentioned by Dr. Sadler are the result of careful analysis. One cause of ectopic pregnancy is salpingitis, but it is not the chief cause. I was reminded of a case I saw in consultation with Dr. Corbett. It was the most remarkable case I have seen in ectopic pregnancy. He had made a correct diagnosis of intraligamentous rupture, operated on her and found there was an intraligamentous ruptured ectopic pregnancy. He thought he better operate that woman extraperitoneally. He thought he cleaned out an ectopic pregnancy in the broad ligament. A few weeks later, when the patient came back to him and said she was getting bigger, he examined her and found she was pregnant—supposedly intra-uterine. Then he thought he had made an error in the diagnosis of the ectopic pregnancy. He watched her through her pregnancy and she came to labor. His diagnosis was correct. She had what is called a false labor and the baby died. I was called in consultation, and I said—you have an abdominal pregnancy. The intraligamentous pregnancy had terminated as an abdominal pregnancy. That was just at the time that the method of taking care of abdominal pregnancy was opening them up, taking out the baby, and leaving the placenta and then allowing it to slowly drain out. Then he had to operate on the woman another time because in the tract of the drainage the woman had a twisting of the tube around this and had a stoppage. He had to operate that woman four times.

A careful analysis from every point of view in over 100 cases of any kind is always of value.

DR. E. A. REGNIER, Minneapolis: I want to compliment Dr. Sadler on his analysis of these 100 cases. His discussion was well presented and brought out all the essential facts pertinent to these cases. The most striking of these facts is the low mortality rate. An operative mortality of 1 per cent in any field of surgery is remarkably low, but most significant in ectopic preg-

nancy. I believe Dr. Sadler will agree that the blood bank at the General Hospital is responsible, in a great measure, for saving the lives of some of these people. I believe that the low operative mortality in this series attests to the fact that diligence on the part of the House Staff and the operators has been well rewarded.

DR. R. T. LA VAKE, Minneapolis: I welcome the opportunity of congratulating Dr. Sadler on this most interesting and instructive thesis. All of us have developed our ideas as to the best approach to the diagnosis and treatment of this condition. I have only agreement and commendation for his conclusions.

Having had occasion to review the files of the Minneapolis General Hospital from 1915 on, it seems to me that before rupture one may expect an error of around 50 per cent in the accuracy of diagnosis, and an error of less than 25 per cent after rupture. The crux of the problem is surgical judgment as to which abdomen should be explored, if in doubt as to diagnosis, and which may be watched. As Dr. Sadler says, we should operate as soon as we are convinced that the history and signs point to a probable ectopic, and should be prepared for blood transfusion. The blood bank has improved tremendously the possibility of success in emergencies. The difficulty of a correct diagnosis is exemplified by the last three cases, in which, in multiple consultations, the diagnosis of ectopic was made. All gave a history of missing a period, spotting, excruciating pain and fainting, and showed slight enlargement and softening of the uterus, and showed a tender mass at the side of the uterus. In one instance under observation the hemoglobin fell 20 points. Two of the three diagnoses proved to be incorrect. One was a very early tubal pregnancy, one was a normal pregnancy complicated by appendicitis, and the other was a normal pregnancy complicated by adhesions from an old operation.

In my opinion, it should be stressed that where a suspicion of possible ectopic exists, a midline incision should always be made. The wisdom of this routine was brought home after watching a surgeon attempt to take care of an interstitial ruptured ectopic through a McBurney incision, used after a thorough study had convinced him that the diagnosis was appendicitis. If the possibility of ectopic exists, use a midline incision.

Now, as to the causes of ectopic pregnancies. It is obvious that any obstruction that will permit the entrance of spermatozoa, but not the egress of the enlarging fertilized ovum, may cause ectopic. In addition, it seems likely, from the phylogenetic history of the fertilized ovum and its usual place of final burrowing in, that, though the usual place of final burrowing is near the fundus, if the fertilized ovum were especially virulent proteolytically, it might burrow in before reaching the uterus; or, if especially weak proteolytically, it might be carried near the internal os before attachment, with the formation of placenta previa. From this standpoint, an ectopic may be regarded as the opposite extreme of the condition furthering placenta previa. This hypothesis is converged upon by the data furnished by those cases where, after an ectopic on one side, a woman successfully passes several fertilized ova through the remaining tube, thereby pointing to the normality of the remaining tube, and yet subsequently she has an ectopic in that tube. This hypothesis, whether correct or incorrect, has the merit of increasing vigilance in watching for an ectopic in the remaining tube. Furthermore, the inherent weakness of the developing fetus, arising from an ovum weak proteolytically, may account in part for the fact that, as compared with prematures of the same age, there is an increased fetal mortality among placenta previa prematures, even where hemorrhage has been slight and delivery has been by Cesarean.

DR. A. G. SCHULZE, Saint Paul: Somebody has referred to the pre-eclamptic and eclamptic toxemias of

REPORTS AND ANNOUNCEMENTS

pregnancy as a disease of theories. One can refer to ectopic pregnancy as being the disease of mistaken diagnosis. There is no other pelvic condition more frequently accused of being present when it is not, or of being overlooked when it is present. In a case where there are signs of rupture and intra-abdominal hemorrhage, the condition is easily diagnosed; but that variety of ectopic pregnancy which is lacking in striking symptoms is more difficult of diagnosis. Nor should one wait and refrain from making a diagnosis until the whole array of textbook symptoms are present. If speed is not an element in the diagnosis, it might be wise to resort to a Friedman test and see what that shows. It may be better to operate and make the diagnosis afterwards. With a midline incision, the whole pelvis can be explored and the appendix removed if need be. Many times the ectopic pregnancy is not on the same side as the one where the patient locates her symptoms.

DR. LITZENBERG: When was the blood bank established?

DR. SADLER: In the Fall of 1937. These cases fall into the group of six years before the blood bank and three years after.

DR. SADLER (in closing): I want to thank you gentlemen for your generous discussion. I may say to Dr. Regnier that, as I showed in Table I, the operative mortality in 900 cases is approximately 3 per cent.

Availability of blood from the blood bank was instrumental in saving two of these women, who received 3600 cc. and 4000 cc. of blood respectively over a period of a few hours. Had we lost them, our mortality would have been 3 per cent instead of the favorably low 1 per cent.

Dr. LaVake brought up several points about the diagnosis of unruptured ectopic. He suggests 50 per cent of unruptured ectopics should be diagnosed—we were not that good. We had thirteen, and of these three were definitely diagnosed; in four, ectopic was suspected; and the diagnosis was missed entirely in six. This was the second admission to the hospital for two of these patients. Another point Dr. LaVake made is about operating for ectopic and finding out your diagnosis is incorrect. Unfortunately, with our system of filing at the General Hospital, it is almost impossible to dig out those cases and give the statistics. I think it would interest you to know that one case we incorrectly diagnosed as ruptured ectopic proved at operation to be a subcapsular rupture of the spleen with massive intraperitoneal hemorrhage.

Dr. Condit announced that Dr. Freeman, member and past president of the Academy, is ill in Abbott Hospital; and he felt the Academy should send him flowers. The Secretary was so instructed.

The meeting adjourned.

E. V. KENEFICK, M.D.

Secretary.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR MAY

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth. Speaker: William A. O'Brien, M.D., Director of Postgraduate Medical Education, Medical School, University of Minnesota.

May 2—Encephalitis

May 9—Poliomyelitis

May 16—Kenny Method

May 23—Crippled Children

May 30—Dental Deformities.

A.M.G.A. GOLF TOURNAMENT

The American Medical Golfing Association will hold its twenty-eighth annual tournament at Seaview Country Club, Atlantic City, on Monday, June 8. Forty trophies and prizes will be awarded.

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the American Medical Golfing Association. Write Executive Secretary Bill Burns, 2020 Olds Tower, Lansing, Michigan, for an application blank. Participants in the American Medical Golfing Association tournament are required to present their home club handicap, signed by the club secretary, at the first tee on the day of play. No handicap over thirty is allowed. Only Active Fellows of the American Medical Golfing Association may compete for prizes. No trophy is awarded a Fellow who is absent from the annual dinner.

JOINT MEETING OF WABASHA, WINONA SOCIETIES

The eleventh annual joint meeting of the Wabasha and Winona County Medical Societies was held April 13 at Buena Vista Sanatorium. Thirty-four persons attended the dinner, at which Dr. Robert A. Glabe of Plainview was toastmaster.

The program arranged by Dr. F. C. Welton, superintendent and medical director of the sanatorium, included the following medical papers:

"Local Manifestations of Constitutional Disease"—Dr. G. L. Loomis of Winona.

"Intrathoracic Tumors" (illustrated with slides)—Dr. T. J. Kinsella of Minneapolis.

Dr. H. Z. Giffin of Rochester, president of the Minnesota State Medical Association, addressed the societies on matters pertaining to public health and medical defense. He explained the functions of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians.

WASHINGTON COUNTY

The monthly meeting of the Washington County Medical Society was held April 14.

After dinner, matters of local interest were considered, after which E. M. Jones, M.D., of Saint Paul gave an illustrated lecture on Periduodenal Hernias. This provoked many questions from the unusualness of this displacement, which were cheerfully and efficiently answered.

MAJOR PLASTER BANDAGES

**NOW ... A Plaster Bandage That
UNWRAPS ... at LESS than you pay for
Ordinary Plaster Bandages**

To remove major casts, either immerse or syringe with hot water, 130° F. The plaster

will disintegrate in one to two minutes and the bandages will unwrap as easily as plain gauze.

Major casts may be bivalved for early therapy. The technic is very simple, requiring only a syringe and bandage scissor. This new plaster bandage is lighter in weight, too, and much cleaner to use.

BECK-LEE ELECTROCARDIOGRAPH

Designed by Charles F. Hindle

The Beck-Lee Electrocardiograph is designed and manufactured under the supervision of Charles F. Hindle—who manufactured the first American made electrocardiograph in 1914.

It employs a genuine quartz-string galvanometer. This Einthoven type galvanometer has long been recognized as the standard of laboratory accuracy in electrocardiography.

The control panel has been simplified so that ease of operation is obtained without sacrifice from accuracy. With each instrument, there is furnished free of charge a book which concisely covers the operation of the electrocardiograph, the interpretation of the electrocardiogram and its correlation with other clinical data.

Each instrument is equipped with all necessary accessories and is ready for use.

Because of quantity production, we are now able to offer the Beck-Lee Electrocardiograph at a very low initial cost.

Write for catalog M-542 and a free demonstration in your office.

WOMAN'S AUXILIARY

MRS. JOHN J. RYAN, *President*
Saint Paul, Minnesota
MRS. L. R. BOIES, *Publicity Chairman*
Knollwood, Hopkins, Minnesota

Mrs. John J. Ryan, President of the State Auxiliary, desired that all counties inform her of any change in officers. Also, any Auxiliary members going to the American Medical Association convention in Atlantic City, should be sure to communicate with her regarding a delegate's card.

The revision committee composed of Mrs. John J. Ryan and Mrs. J. S. Reynolds, with Mrs. M. S. Henderson, as chairman, met April 14 to consider changes in the State Auxiliary constitution.

Last call for reservations for the Twentieth Annual Convention of the Woman's Auxiliary to the American Medical Association, to be held at Haddon Hall, Atlantic City, New Jersey, June 8-12.

Atlantic City extends a hearty welcome to you!

County News

Stearns-Benton.—The regular dinner meeting of the Stearns-Benton Medical Auxiliary was held at Hays House, St. Cloud, Thursday, March 27. Mrs. P. E. Barringer presided. Plans for a post Easter card party were made and Mrs. J. P. McDowell was appointed to take charge. Out-of-town members present were: Mmes. S. H. Koop, Richmond, E. E. Keithohn, Kimball, and Joseph Barnett, Cold Spring. After the business meeting, the group attended an illustrated lecture on Vitamins given by Dr. J. J. Boehrler, University of Minnesota.

Goodhue.—The March meeting of the Auxiliary was held at the home of Mrs. H. Claydon, Red Wing. There was a rehearsal of the puppet show on Preventive Medicine. As a special project, it was voted to furnish a room at the Cannon Falls Tuberculosis Sanatorium. Mrs. L. E. Claydon assisted in serving the buffet lunch which followed.

Ramsey.—At the recent State Auxiliary Board meeting, Mrs. Mark Ryan gave a most interesting report of concentrated efforts in different phases of Red Cross work. To date the number of working hours members have put into this work includes the following:

- Knitting, 2,650.
- Nutrition classwork, 200.
- Home Nursing Classes, 160.
- Sewing, 1,115.
- Surgical dressings, 2,255.
- First aid class, 275.
- Canteen work, 75.

Mrs. Edward V. Goltz was chairman of the entertainment committee for visiting women of the 26th annual session of the American College of Physicians held in Saint Paul April 20-24.

On Monday a welcoming tea was given at the University Club at which the Ramsey County Auxiliary was co-hostess, Mrs. Douglas Brand and Mrs. Harry Ghent representing the Auxiliary.

On Tuesday a luncheon and style revue was given at the Hotel Lowry and members and guests attended the entertainment in the evening furnished by the Ramsey County Medical Society in the theater of the municipal Auditorium.

On Wednesday a tour of the Radiation Therapy Department of the University of Minnesota was made in the morning, followed by luncheon at the Coffman

Memorial Union. The President's reception and dance was held at Hotel Lowry in the evening.

On Thursday a breakfast for members and guests was given at the Lowry Hotel, followed by a tour of the city. The annual banquet of the college was held in the ballroom of the Lowry Hotel in the evening.

St. Louis.—The March meeting of the Auxiliary took place at the Woman's Club.

Duluth medical women have gone a long way in doing their part in war work. They have contributed a remarkable amount of material and assistance in various forms of National Defense and International war relief since the latter part of last year. In coöperation with the Civilian Defense Council and the American Red Cross, the St. Louis Auxiliary helped institute a program to train women for actual defense occupations. The Women's Volunteer office was opened November 24 at 210 Alworth Building, under the direction of Mrs. D. W. Wheeler and seventy-five volunteer assistants. This office is maintained by the auxiliary members Mondays through Fridays from 10:00 a.m. to 4:30 p.m. and from 10:00 a.m. to 1:00 p.m. Saturdays, for women who wish to sign up for nutrition classes, motor corps, first aid, canteen corps, and nurses' aides.

Hennepin.—The Auxiliary held its thirty-first annual post-Easter party Monday, April 6, to raise funds for its philanthropies. Contributions are given for Cancer Control work; to Sarahurst, a rehabilitation home for former tuberculosis patients; for the book fund at Glen Lake Sanatorium; and for a medical service fund which is used in isolated cases by Hennepin County Medical Society.

Mrs. R. S. Ylvisaker, chairman, and Mrs. M. H. Seifert, co-chairman, were assisted by the key women in the various units over the city. Because of the serious times, twenty-two units chose to contribute money, while five groups had parties. Considering everything, the undertaking was very successful.

Renville.—The regular meeting of the Renville County Auxiliary was held in Olivia, Tuesday, March 9.

State Board Meeting

The mid-winter board meeting of the Woman's Auxiliary was held Friday, March 20, at the Curtis Hotel in Minneapolis. County presidents and the different committee chairmen in attendance gave brief reports of their year's work.

A letter of resignation from Mrs. W. W. Moir, president-elect, was read. Mrs. R. J. Josewski, Stillwater, was elected to fill this vacancy. Mrs. J. R. Peterson, Minneapolis, was elected to fill the office of first vice president.

The nominating committee chosen by the assembly consists of the following members: Mrs. James Blake, Sr., Hopkins; Mrs. A. J. Bianco, Duluth; Mrs. Edmund W. Miller, St. Peter; Mrs. Harold Wahlquist, Minneapolis; Mrs. E. M. Hammes, Saint Paul.

The luncheon following the meeting was arranged by Mrs. J. M. Neal, Minneapolis. About forty were present. Dr. Ernest Lundy, Rochester, was the guest speaker and presented talks and film productions on "First Aid" and "Firebombs."

Don't Wait Too Long

It's time to think of hot weather and fans once more. This year try one of the modern KISCO CIRCULAIR units, and you'll be glad your old fan is worn out.

These clever fans lift the cooler air up and distribute it in all directions at one time.

And don't wait too long—as you know—deliveries are pretty irregular these days.

Illustrated, a handy model for your desk. Approximately 8 inches in diameter and 9 inches high.

* * *

Dr. Glenn H. Leemhuis, physician at McGregor for the past several years, opened offices in Aitkin last month. He will move his family there.

Dr. John F. Kelly, who expects to be called into active duty with the Medical Corps soon, concluded his medical practice in Aitkin April 1 and returned to his home in Richmond. He had practiced in Aitkin since June 15, 1941.

Effective, Convenient and Economical

THE effectiveness of Mercurochrome has been demonstrated by twenty years' extensive clinical use.

For the convenience of physicians Mercurochrome is supplied in four forms—Aqueous Solution for the treatment of wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

Mercurochrome, H.W.&D.
(dibrom-oxymercuri-fluorescein-sodium)

is economical because solutions may be dispensed at low cost. Stock solutions keep indefinitely.

Mercurochrome is accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

Dr. Frank E. Burch of Saint Paul discussed two papers, "Cataracts" and "Glaucoma" at the meeting of the Florida Society of Ophthalmology and Otolaryngology in Hollywood, Florida, April 13-15, held in conjunction with the annual session of the Florida Medical Association.

* * *

Dr. Elexious T. Bell, head of the department of pathology at the University of Minnesota Medical School, will present three lectures at the meeting of the Texas State Medical Society in Houston, May 11-14.

Dr. Bell delivered a graduate lecture under the auspices of the Polk County Medical Society in Des Moines, March 18. His subject was "Kidney Disease."

* * *

Participating in a series of regional war conferences sponsored by the American College of Surgeons is Dr. Harold S. Diehl of Minneapolis, dean of medical sciences at the University of Minnesota. He spoke last month at meetings in Portland, Oregon; San Francisco and Los Angeles as representative of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians of the Office of Defense, Health and Welfare Services, of which he is a member.

* * *

Dr. Earl J. Black has opened offices for the practice of internal medicine at 1253 Lowry Medical Arts Building, Saint Paul, in association with Dr. Everett K. Geer. Dr. Black was a resident in medicine and assistant superintendent at the Ancker Hospital for a number of years. He will continue his association with the hospital in a part-time capacity as head of the outpatient department of the tuberculosis sanitarium at Ancker.

* * *

From the United States General Hospital Unit No. 26, now at Fort Sill, Oklahoma, for a training period comes news of two weddings.

Dr. Robert Hebbel, major, and head of the unit's laboratory service, married Miss Beulah Agre, technician at the University of Minnesota Hospitals, February 27, at Fort Sill.

Dr. Stanley W. Lundblad, Minneapolis, and Miss Alice Lindquist were married February 26 at Fort Sill. Dr. Lundblad is a captain in the Medical Service.

* * *

When the California State Medical Association meet in Del Monte, May 4, 5 and 6, Dr. Wallace Cole of Saint Paul will present three papers. He will discuss the Kenny technique for treatment of infantile paralysis fractures, and also war wounds.

Dr. Cole discussed the Kenny technique at two meetings in the East recently. He addressed the Westchester County Medical Society at White Plains, New York, March 17, and Group I of the American Academy of Pediatrics in Philadelphia, April 3.

* * *

A continuation course in obstetrical problems will be presented for physicians May 14, 15 and 16 at the University of Minnesota Center for Continuation Study. The course is under the auspices of the University Medical School, the Minnesota State Department of Health and the Minnesota State Medical Association.

OF GENERAL INTEREST

A course in maternity and new-born nursing was presented for nurses at the Center, April 30-May 2, under the sponsorship of the Minnesota State Department of Health, the Minnesota Nurses Association, and the University Medical School.

* * *

Several University of Minnesota men participated in symposia at the American Physiological Society meeting in Boston, April 1-3. Dr. Maurice B. Visscher, head of the division of general physiology, discussed gastric secretions when he contributed to a symposium on "Mechanism of Secretion." Dr. George O. Burr, director of the division of physiological chemistry, discussed the significance of the essential fatty acids in another symposium; and Dr. Wallace D. Armstrong, also of that division, discussed the development of bones and teeth in a symposium on nutrition.

* * *

The Dakota County Medical Society met with officers of the Minnesota State Medical Association, Friday, April 10, in Saint Paul.

Officers elected at the meeting are: Dr. L. S. Burns, South Saint Paul, president; Dr. A. J. Edmond, Farmington, vice president; Dr. A. H. Field, Farmington, secretary-treasurer; Dr. L. D. Peck, Hastings, delegate; Dr. J. A. Sanford, Farmington, alternate.

* * *

Dr. Wesley W. Spink, associate professor of medicine in the Medical School, University of Minnesota, was

elected to full fellowship in the American College of Physicians during its recent meetings in Saint Paul. Ordinarily full fellowship is granted only to doctors who have hitherto been associates of the college. Successful pioneering work in the use of new drugs, especially the sulphha compounds, led to Dr. Spink's election, it was announced.

* * *

Dr. Cecil J. Watson, director of the division of internal medicine at the University of Minnesota Medical School, will present several papers at the annual meeting of the Illinois State Medical Association in Springfield, May 19-21.

Dr. Watson also read a paper before the Association of American Physicians which met in Atlantic City, May 5-6. While in Atlantic City he attended sessions of the American Society for Clinical Investigation, as did Dr. Wesley W. Spink, also of the division of internal medicine.

* * *

The annual Medical Six O'clock banquet was staged Thursday, April 30, in the ballroom of Coffman Memorial Union on the University of Minnesota campus.

Sponsored by Incus, an organization of representatives of the student body, the dinner was for the entire medical school—faculty, students, alumni and their families. It is the only social function of the year at which the entire school gets together.

Toastmaster was Dr. William A. O'Brien, director of postgraduate education. Speakers included Dr. Law-

Minnesota people who participated in the Second American Congress on Obstetrics and Gynecology at St. Louis, Missouri, April 6-10, included: Dr. A. L. Dippel, University Hospitals, who participated in demonstrations: Dr. Jennings C. Litzenberg of Minneapolis, who was chairman of a sectional meeting on Post-Graduate Education and Maternity Hospital Management; Dr. Robert D. Mussey, of Rochester, who conducted a round table discussion; Dr. Alex E. Brown, Dr. Stuart W. Harrington and Dr. Lawrence M. Randall of Rochester, and Miss Frances Hoffert, R.N., teaching supervisor in obstetrics at Minneapolis General Hospital, who presented papers.

Others who attended included: Dr. Viktor O. Wilson, Miss Adelia Egggestine and Miss Ethel McClure of the Division of Child Hygiene, Minnesota State Department of Health.

* * *

In the East to attend several pediatric meetings are five members of the University of Minnesota pediatrics department: Dr. Irvine McQuarrie, Dr. Arild E. Hansen, Dr. Albert V. Stoesser, Dr. Marguerite Booth and Dr. John A. Anderson.

On April 29, they attended the Society for Pediatrics Research which met at Skytop, Pennsylvania, Dr. Anderson presenting a paper on "Human Diabetes Insipidus," and Drs. Booth and Stoesser, a paper on bronchial asthma in children.

At the American Pediatrics Society meeting, also in Skytop, April 30 to May 2, Dr. Hansen gave a paper on the "Relations of Lipids to Eczema" and Dr. McQuarrie one on "Electrolyte Disturbances of Tumors of the Adrenal Cortex."

On May 4, the group was in Atlantic City for the meeting of the American Society for Clinical Investigation. Here Dr. Hansen addressed the meeting on "Relations of Fat Metabolism to the Nutrition of the Skin."

Dr. Hansen and Dr. McQuarrie will also attend the annual session of the American Academy of Pediatrics, May 13-15, in Cleveland. The latter will take part in a symposium on allergy, discussing "Metabolic Aspects of Allergic Disorders," and will also help to conduct special examinations for certification by the American Board of Pediatrics.

Hospital News

Wesley Sherman of Minneapolis is the new business manager of the Itasca Hospital in Grand Rapids. Mr. Sherman received his training at the University of Oklahoma, and his practical experience at the University Hospitals in Minneapolis under Ray Amberg.

Officers of the Glencoe Municipal Hospital in Glenocoe were reelected at the recent annual meeting. J. H. Holmes is president; William J. Harpel, vice president; Cedric Linville, secretary-treasurer.

Dr. H. H. Holm is head of the hospital staff; Dr. W. R. Schmidt, vice president; Dr. H. C. Goss, secretary-treasurer. Dr. A. R. Neumaier is a member of the staff.

Applications from the following physicians for staff membership were accepted: Dr. M. J. McMahon of Green Isle, Dr. Alvin M. Jensen of Brownston, Dr. J. D. Selmo and Dr. E. J. Eklund of Norwood, Dr. T. P. Martin of Arlington and Dr. T. J. Trutna of Silver Lake.

Miss Clara Draxton, hospital superintendent, reported on the purchases of equipment for the hospital.

* * *

Several members of the staff of the United States General Hospital Unit No. 26 whose orders were delayed have joined the unit in Fort Sill, Oklahoma. They include: Dr. Randall S. Derifield, captain, Medical Service; Dr. John D. Galloway, captain, Surgical Service; Dr. Paul Kabler, captain, Laboratory Service; Dr. Oscar Lipschultz, major, Dr. Jack Chalek, captain, and Dr. Eugene Ahern, first lieutenant, of the X-ray Service.

Continuation Course in Internal Medicine

Minnesota men who were registrants for the Continuation Course in Internal Medicine given April 6-18 at the University of Minnesota Center for Continuation Study were: Dr. Stanley T. Kucera, Lonsdale; Dr. Arnold Larson, Detroit Lakes; and Dr. Royal V. Sherman, Red Wing.

Guest members of the faculty included: Dr. Theodore L. Althausen, associate professor of medicine at the University of California Medical School; Dr. Alvin F. Coburn, assistant professor of medicine at Columbia University College of Physicians and Surgeons, New York City; Dr. Willis H. Fowler, associate professor of medicine, State University of Iowa, College of Medicine, Iowa City; Dr. Philip Levine, bacteriologist and serologist, Newark Beth Israel Hospital, Newark, New Jersey; Dr. Thomas T. Mackie, clinical assistant professor of medicine, Columbia University College of Physicians and Surgeons, New York City, and Dr. William S. Middleton and Dr. Elmer L. Seeringhaus, professors of medicine, University of Wisconsin Medical School, Madison.

Special events during the course included: the Hennepin County Medical Society lecture, April 6, at which Dr. Middleton spoke on "Some Rationalized Therapeutic Experiences"; the Minnesota Pathological Society annual lecture, April 7, given by Dr. Coburn on the subject, "Role of Hemolytic Streptococcus in Pathogenesis of Rheumatic Fever"; the Dight Institute lecture, April 10, at which Dr. Philip Levine spoke on "Serological Differentiation of Human Blood, Theoretical and Practical Considerations"; the Franklin R. Wright Memorial Lecture, April 14, at which Dr. Charles Huggins of the University of Chicago spoke on "Endocrine Relationships of Prostatic Carcinoma" and the George Chase Christian Lecture on "Recent Trends in Cancer Research" by Dr. H. B. Anderson, principal biologist, National Cancer Institute, April 15.

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

In Memoriam

Hallward Martin Blegen

Dr. Hallward Martin Blegen of Warren, Minnesota, died March 26, 1942 at the University Hospital, Minneapolis, at the age of fifty-six.

Dr. Blegen was born in Rochester, Minnesota, August 7, 1885. He graduated from Augsburg Seminary, Minneapolis, in 1904 and received his medical degree from the University of Minnesota medical school in 1909. After serving as interne at the Minneapolis General Hospital, he was city physician for Minneapolis from 1910 to 1912, and since 1916 had practiced in Warren.

Dr. Blegen had been president of the Warren Board of Education for the past twenty years. He also had been coroner of Marshall County, surgeon for the Great Northern and Soo Line Railroads, chief of staff of the Warren Hospital and a past president of the Red River Valley Medical Society.

Besides his wife, Clara, Dr. Blegen is survived by a daughter, Mrs. Bernard Gimmetad, Minneapolis; a son, Dr. H. M. Blegen, Jr. of Missoula, Montana; two sisters, Martha Blegen of Minneapolis and Anne H. Blegen, professor of French at Saint Olaf College in Northfield; and three brothers, Professor Carl V. Blegen of the University of Cincinnati; Theodore C. Blegen, dean of the graduate school of the University of Minnesota and John E. Blegen of Minneapolis.

Arthur Burns

Word has been received of the death of Dr. Arthur Burns on April 8, 1941. He was formerly a Fellow in Medicine in the Mayo Foundation.

Dr. Burns was born in Cuero, Texas, in 1896. He received the degree of M.D. in 1923 from Johns Hopkins University, and was an intern at the Bay View Hospital in Baltimore from July 1, 1923, to July 1, 1924. He was a Fellow in Medicine in the Mayo Foundation from July 1, 1924, to October 1, 1926, when he left to practice medicine at the Burns Hospital in Cuero.

He was a member of the American Medical Association, the Alumni Association of the Mayo Foundation, Phi Delta Theta and Phi Chi.

Approximately one person out of twenty-five has difficulty in *hearing* in the average auditorium, as compared with one out of 125 who has trouble in hearing a direct conversation.

A single *house fly*, if all of its descendants lived and bred, would be the ancestor of 2,000,000 flies at the end of one summer.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

NEUROANATOMY. Fred A. Mettler, A.M., M.D., Ph.D. Professor of Anatomy, University of Georgia School of Medicine, Augusta, Georgia. 476 pages. Illus. Price, \$7.50. Cloth. St. Louis: C. V. Mosby Co., 1942.

In the Preface the author states that to the medical student it is impossible to form clear conceptions of microscopic neuroanatomy until he has a firm grasp of the gross aspects of the neural system. Part I, to which 164 pages are devoted, concerns "Gross Aspects of the Neural System." The text of the remaining pages, Part II, deals with "Microscopic Anatomy of the Neural System." The book contains 337 illustrations, 30 in color; these should prove very serviceable. There is a fifty-three page list of selected references, in addition to an author and subject index. The book deserves a favorable reception.

BUY WAR BONDS

(Continued from Page 377)

these may be purchased by associations and corporations as well as individuals. The F Bonds are twelve-year bonds which provide a return equivalent to an annual interest rate of 2.53 per cent. The smallest costs \$18.50 and pays \$25 in twelve years; the largest costs \$7,400 and pays \$10,000 at maturity. Bonds of Series G are sold at par in denominations from \$100 to \$10,000, and these bonds pay interests at the rate of 2.5 per cent throughout their twelve-year maturity period.

Freedom Bonds, Victory Bonds—we must buy and continue to buy these war securities. We must put our dollars into the front line battle in America's fight for freedom.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

(Continued from Page 380)

Board of Medical Examiners, that he had performed a previous criminal abortion on the same girl in December, 1941, for which he was paid \$50.00. He also admitted that he had performed at least seven or eight other criminal abortions during 1941, and had performed others prior to that time.

The defendant graduated from the Des Moines Still College of Osteopathy in 1913. He was licensed in Minnesota in the same year, and has practiced at Hutchinson for the past thirteen years. Prior to that time he practiced at Redwood Falls and Madelia. From 1937 to 1941 the defendant was also Judge of the Municipal Court at Hutchinson. The case has been referred to the State Board of Osteopathic Examiners for such action as they may decide to take in reference to a revocation of the defendant's osteopathic license.

FOR NERVOUS DISORDERS

Operated In Connection

with

Homewood Hospital

Plymouth at Penn Avenue, Minneapolis

The leading psychiatrists of the country agree on one fact, the first essential in the treatment of any nervous disorder is isolation. The preferable way to attain this end is proper hospital construction. The cottage style of hospitalization is the latest in the treatment of these patients. In our new arrangement, we are providing just this type of accommodation. We have six distinct units to accommodate all types of patients, large acreage of elevated, beautiful lands surrounded by parks, lakes and woods. Our nurses training school furnishes the best in psychiatric nursing service.

A nonprofit organization open to the medical profession.

SAFETY LENSES

HARDRx Prescription lenses are for general use and are tempered for increased margin of safety against breakage.

BENSAFE Prescription Safety lenses are of heavier construction and hardened for industrial and hazardous sports wear.

Both are of highest quality and are case hardened by a controlled heat treatment. Each HardRx lens is subjected to impact of $\frac{1}{2}$ " steel ball dropped one meter and Bensafe lens to $\frac{3}{4}$ " steel ball dropped one meter.

THE CIGARETTE OF COSTLIER TOBACCOS

All-out efforts for a successful conclusion of hostilities demand the hands, brains and hearts of every American. Maintenance of maximum efficiency requires a healthy, well-nourished body. Our men in the armed forces are assured of nutritionally balanced meals, but, the folks at home also need proper nourishment so that they can do

their jobs . . . so important to the men in the field.

COCOMALT, daily, is an excellent "defense" addition to meals. More and more, physicians are recommending this delicious drink for the entire family. This enriched food drink contains vitamins A, B₁ and D as well as the minerals, calcium, phosphorus and iron.

A New Clinical Study has again shown the value of COCOMALT in therapeutic diets. Have you sent for your copy of "The Use of a Malted Food Preparation as a Dietary Supplement in Pulmonary Tuberculosis"?

Cocomalt *Enriched Food Drink*

A Brilliant Record

OF EFFECTIVENESS AND SAFETY

The two prime requisites of an antiluetic, effectiveness and safety, are fulfilled in Mapharsen.* Scores of medical papers during the last decade record its relative safety and low incidence of reactions in comparison with other arsenicals.

A review of the literature since 1935 reports on 269,326 injections of Mapharsen with a ratio of one death to 67,332 patients, which is less than one-half the death rate from neoarsphenamine.¹ Only six fatalities have been reported from several million doses of Mapharsen.

Mapharsen (meta-amino-para-hydroxy-phenylarsine oxide hydrochloride) contains 29 per cent arsenic in trivalent form and requires only one-tenth the arsenical dosage of arsphenamine. It is decidedly convenient to use as it does not require neutralization before injection.

FOR SALE BY SURGICAL DEALERS AND DRUGGISTS

The "troublesome weed" will soon harass
your patients with contact dermatitis—

POISON IVY EXTRACT

Lederle

THE OLD BUGABOO OF VACATIONISTS, poison ivy, will soon rear its ugly head! In the spring and summer the plant is most poisonous, as it is then loaded with sap and its leaves and stem are more susceptible to injury.

The prophylactic injection of "Poison Ivy Extract *Lederle*"* can establish a complete immunity to the usual direct contact with *Rhus toxicodendron radicans* in at least a considerable proportion of susceptible persons. Two injections, given within a two-week interval, are sufficient to protect a large proportion of such persons against the inconvenient and distressing dermatitis resulting from ivy poisoning. This should be of interest to farmers and military land forces at this time as well as to vacationists.

In the treatment of ivy poisoning, one or two injections of "Poison Ivy Extract *Lederle*" often give marked relief within a short time.

Pain on injection is seldom experienced with the Lederle extract, which is an *acetone extract in almond oil*. Literature on the details of this treatment available to the physician on request.

PACKAGES:

2 syringes (1 cc. each)
1 syringe (1 cc.)

*"Poison Oak Extract *Lederle*" is available for the Pacific Coast states.

LEDERLE LABORATORIES, INC.

Are the Neuritic Symptoms of Pregnancy *due to a deficiency* of vitamin B₁ (thiamine)?

SUCH common neuritic symptoms of pregnancy as pains in arms and legs, muscle weakness, and (less frequent but more serious) paralysis of the extremities may result from a shortage of antineuritic vitamins, recent investigations appear to show. Although neuronitis of pregnancy has long been considered a toxemia, no toxins have ever been identified.

Clinical observations of Strauss and McDonald lead to the conclusion that the condition is a dietary deficiency disorder similar to beriberi, caused by lack of vitamin B₁. They report recovery in their cases receiving this therapy, including dried brewers' yeast.

Hyperemesis as Cause of Avitaminosis

Wechsler observes that all cases of polyneuritis of pregnancy recorded in the literature were preceded by long periods of severe vomiting. "It would seem," he adds, "that because of actual starvation these patients suffered from avitaminosis and consequent neuritis," a view likewise held by Hirst, Luikart, and Gustafson. Plass and Mengert observe that the practice of giving high carbohydrate feedings for hyperemesis gravidarum is still more likely to cause avitaminosis.

Dried brewers' yeast, as it is far richer than any other food in vitamin B₁ (thiamine), is being used with benefit both in the prevention and treatment of polyneuritic symptoms of pregnancy. Lewy found that additions of yeast to the diet reduced electric irritability of the peripheral nerves and brought clinical improvement. Vorhaus states that he and his associates, after administering large amounts of vitamin B₁ (thiamine) to 250 patients having various types of neuritis, including that of pregnancy, observed in about 90% of cases "varying degrees of improvement, i.e., from partial relief of pain to complete disappearance of all symptoms."

Need for Vitamin B₁ (thiamine) in Lactation

Evans and Burr, Hartwell, Sure and co-workers, and Macy *et al* are among numerous authorities who find that the nursing mother also needs a supplement of vitamin B₁ (thiamine) from 3 to 5 times the normal requirement. It is accepted that during pregnancy and lactation the requirement for vitamin G (riboflavin) is increased.

Consisting of nonviable yeast, Mead's Brewers Yeast Tablets offer not less than 50 International vitamin B₁ (thiamine) units and 50 Sherman vitamin G (riboflavin) units per gram (20 International units of vitamin B₁ and 20 Sherman units of vitamin G per tablet).

Supplied in bottles of 250 and 1,000 tablets, also in 6-oz. bottles of powder.

For Infants and Children

● Vitamin D becomes an integral part of milk when it is added in the form of Drisdol in Propylene Glycol. Administration of the anti-rachitic vitamin is thus made simple and easy. Relatively small doses suffice for the prevention of rickets—2 drops in the daily milk ration.

Drisdol in Propylene Glycol

does not float on milk

does not adhere to bottle

does not have a fishy taste

does not have a fishy odor

Drisdol in Propylene Glycol—10,000 units per gram—is available in bottles containing 5 cc. and 50 cc. A special dropper delivering 250 U.S.P. vitamin D units per drop is supplied with each bottle.

LACTOGEN
approximates
women's milk in the
proportion of
food substances

THE cows' milk used for Lactogen is scientifically modified for infant feeding. This modification is effected by the addition of milk fat and milk sugar in definite proportions. When Lactogen is properly diluted with water it results in a formula containing the food substances—fat, carbohydrate, protein, and ash—in approximately the same proportion as they exist in women's milk.

No advertising or feeding directions, except to physicians. For free samples and literature, send your professional blank to "Lactogen Dept.," Nestlé's Milk Products, Inc., 155 East 44th St., New York, N. Y.

"My own belief is, as already stated, that the average well baby thrives best on artificial foods in which the relations of the fat, sugar, and protein in the mixture are similar to those in human milk."

*John Lovett Morse, A.M., M.D.
Clinical Pediatrics, p. 156.*

Q. Now, Doctor, from your point of view, just what is canning?

A. Well, to me canning is something more than just another method of food preservation; it is one of the important means whereby many foods essential for proper nutrition are made readily available to Americans in all localities during all seasons of the year. (1)

The art of doing things well

SIXTY VIALS a minute, each vial filled with exactly the same amount as its predecessor. A vial every second—aseptically stoppered under protecting glass shields in a room where even the air is filtered. These are the familiar vials of Protamine, Zinc & Iletin (Insulin, Lilly) ready to receive the label which marks their potency. Preparations of Iletin (Insulin, Lilly) are weeks in the making but every minute is spent under the direct control of experts who know the art of doing things well.

HEALTH AND SAFETY OF WAR-TIME WORKERS

LEVERETT D. BRISTOL, M.D., DR. P. H., HEALTH DIRECTOR

American Telephone and Telegraph Company
New York, New York

PROMOTING the health and safety of war-time industrial workers, who produce the materials and carry on the civilian services for the men behind the guns, is of vital concern to the organized medical profession, as well as to all other citizens of the United States. It is my purpose to present this subject under the following five headings: (1) Employee Relations; (2) Management Relations; (3) Medical Relations; (4) Public Health Relations; and (5) Educational Relations. The first two connote the demand or need for industrial health services, the last three—the supply of such services.

Employee Relations

Man power is now the greatest need both of industrial production and of military success. Adequate man power is dependent on the highest type of mental and physical fitness. The speed-up of production, the development of modern material and methods, the increased employment of new workers will require new industrial health and safety routines and regulations, more intensive study of occupational diseases and industrial poisons, and the extension and improvement of all health and safety education. Our present needs require a strengthening and broadening of the entire industrial health and safety program all along the line from private industry to local, state and federal jurisdictions. As emphasized by Surgeon General Parran of the United States Public Health Service, "Industrial hygiene must keep pace with the needs arising from high speed assembly lines, which will employ some fifteen million men and women within the year. Great

Britain learned that it is urgently necessary to have the full-time services of a trained industrial physician in every large plant. Less than one-seventh of our workers have that service now." As a further indication of the need for promoting more adequate health and safety services for wartime workers, is the fact that in 1941, according to the United States Public Health Service, there was a 12 per cent increase in disabling cases of sickness and non-industrial injuries among male employes of various industries as compared with the mean for the last ten years.

An adequate industrial health program should be a strong arm in winning the war, particularly in the preservation of expert workers and assisting in the development of additional skilled workers. Reducing lost time due to occupational and non-occupational illness and accidents, and cutting down excessive exposure to injurious materials are parts of the program which will be conducive to maximum national effectiveness and production. It is particularly necessary that studies be made to determine unfavorable environmental factors in the production and use of war equipment and munitions. Industrial health should involve, primarily, a program of health conservation, emergency care and disease and accident prevention among employees. Industrial medicine, surgery, engineering, toxicology, nursing, record keeping, plant hygiene, sanitary inspection and health and safety education are the chief means for carrying out a program. Too often these have been considered as ends in themselves.

Our active war efforts already are being reflected in rapidly increased industrial activity and

Address presented before the Hennepin County Medical Society, Minneapolis, Minnesota, May 4, 1942.

production in many centers. Added number of workers in a plant, without a corresponding increase in working space, may easily create serious conditions of overcrowding and thus suddenly augment potential industrial sickness and accident hazards. Failure to appreciate the need for a possible change in methods and procedures in the handling of new or increased amounts of chemicals and other substances, may result in serious injury to the health and bodies of workers. Moreover, wartime industrial health problems do not exist in the plant alone; attention must be given also to the home and housing conditions of workers, as well as to their nutrition, recreation and morale or mental health. In various areas and communities, some of which have sprung up "over night," the increasing influx of workers gives the subjects of adequate housing and nutrition particular importance in the war program. In this connection, where possible and feasible, it is suggested that in those industries which do not, during peacetimes, ordinarily provide lunchrooms or cafeterias for the workers, special plant canteens might be set up, under the direction of expert nutritionists, to make available nourishing, energy-building foods as required.

Management Relations

One of the most significant recent developments in relation to business management's organized interest in the health of the worker was the creation of an Advisory Health Committee of the Insurance Department of the Chamber of Commerce of the United States, which held its first meeting in March, 1942. This Committee will consider the possible development of an industrial health program to be carried on by the Chamber in coöperation with affiliated trade associations. It represents a broadening of the health work of the Chamber, which for many years has promoted more adequate city and rural health administration through annual Inter-Chamber Health Conservation contests. The National Association of Manufacturers also has a Committee on Healthful Working Conditions.

In management's organization of personnel for industrial health service, it is assumed that (1) the larger the company, the more specialization and full-time service is possible; and that (2) the smaller the company, the more generalization

is required and the greater is the necessity for the unification of positions and functions, and the need for assistance in industrial health work from part-time private practitioners of medicine and local health departments or associations. The development of a practical program for health supervision of employes of smaller plants and business concerns probably is the greatest unmet need in the whole realm of our wartime industrial health efforts. This should involve, primarily, such activities as (a) employe health and safety control; (b) office and plant hygiene control; (c) health and safety education and (d) an adequate system of records. For smaller business concerns, which employ approximately 85 per cent of all the workers, much of the health and medical services ultimately must be made available either (a) by groups of these smaller concerns working together through some joint plant of centralization—as, for example, those in one building or trade group or in a restricted locality—on the basis of pooling of costs for medical, nursing, and other assistance required; or (b) by local community agencies such as health departments, university institutes of industrial hygiene, or organized local medical societies or groups of physicians.

A wide range of practice exists in larger industries so far as management's organization of medical work is concerned. A majority of these industries have medical units of their own, some of which are highly organized with medical and nursing staffs and all of the modern equipment required. In these units the following services usually are available:

1. First Aid in sickness and accidents.
2. Advice on medical or surgical problems.
3. Attention to ailments of short duration and of a character not requiring absence from work.
4. Laboratory and other examinations in coöperation with employe's physician.
5. Routine physical examinations for employment or placement, or in cases of suspected disease.
6. Periodic health examinations, particularly for those in hazardous occupations.
7. Advice on plant sanitation and hygiene.
8. Preparation of health literature.
9. Coöperative services with Benefit or Sickness Insurance Committees and Compensation Boards.

Most of the larger companies provide nursing services in connection with their medical activities. In fact, industrial nursing is becoming one of the important components of industrial health.

Noteworthy progress also is being made to provide part-time nursing service for small industries by local visiting nursing associations and other groups.

While management as a rule has an abiding interest in the personal health and well-being of each individual worker, the great problems which the manufacturing or business executive must face are those more impersonal mass extravagances of lost time, decreased efficiency and mounting costs—the triple offspring of industrial sickness and accidents. One of the leading management representatives states that absenteeism loss in the United States, or in an individual plant, may be approximated in dollars and cents by multiplying the number of workers by seventy dollars per year. Winning the war requires among other things that these losses be prevented or controlled so far as possible!

Medical Relations

The science and art of industrial health, like the worker whose mental and physical fitness it serves to protect and promote, have evolved through periods of infancy, childhood, and adolescence into vigorous adult life. It may be of interest to emphasize the changing characteristics of organized industrial health promotion through these four periods and to note the relationship of the practitioner of medicine to this development.

Development Periods of Industrial Health

1. *Infancy—Traumatic Surgery.*—A little over twenty-five years ago, interest in the health of workers in various industries of the United States was aroused, particularly by the need for surgical care or treatment of industrial accidental injuries and in the newer compensation cases associated therewith. Traumatic surgery rapidly developed as a specialty, and the company surgeon became the first central figure in the field of early industrial medicine.

2. *Childhood—Accident Prevention.* — The next stage in the development of industrial health as we know it today was that of accident prevention. The key person of this period has been the safety engineer. However, there are important medical aspects of accident control, and the practicing physician working in the industrial

field has much he may contribute to the solution of this problem of accident prevention.

3. *Adolescence—Occupational Disease Control.*—The third stage in our well-rounded development of industrial health in this country has been associated with many significant discoveries in relation to occupational diseases and in the establishment of procedures for their control. The general practitioner of medicine has long had knowledge of the diagnosis and treatment of these conditions, but he has had to depend to a considerable extent on the chemist, the toxicologist, the laboratory expert, the engineer, or the industrial hygienist for much of the recent progress in prevention and the hygiene of the industrial working environment.

4. *Adult Life—Positive Health Promotion and Sickness Prevention.*—While these four periods in the development of organized industrial health work are not mutually exclusive, the present stage of industrial health activities involves positive health promotion and education and sickness and accident prevention on a broad scale. Attention must be given not only to occupational injuries and diseases but also to the prevention and control of non-occupational sickness and accidents, with special reference to the common diseases of the upper respiratory tract, tuberculosis, syphilis, heart disease, diabetes, appendicitis, and arthritis, as well as so-called off-duty accidents in the home and on the public highway. In this complete development of the modern industrial health program the practitioner of medicine will have an increasingly important part to play.

The Physician in Industry

Industrial physicians may be classified into three groups based on the amount of time given to work, viz.: (a) those on full time, (b) those on part time, and (c) those on call for special emergency services.

The full-time industrial physician usually is a member of the company medical department staff on a salaried basis, with special training and experience in industrial medicine. He must assume duties not only as a consulting physician or surgeon but also more or less as the health officer of the company, applying all of the known

principles of preventive medicine and industrial hygiene to the employe group. Part-time physicians give shorter or longer periods of time to services in one or more company plants. They usually are paid a stated sum per week, month, or year by the company in question according to the amount of time given. In general, their activities are associated with physical examinations, case work, and special problems having to do with compensation and other medicolegal matters. Physicians on call serve only on special request. They and the part-time plant physicians are the usual community practitioners and specialists. Up to the present time most of the smaller industrial plants are served by these general practitioners, and industry is making more and more use of such medical knowledge and service. In no sense should the so-called industrial physician be a competitor of the general practitioner in the community. All members of the medical profession, including the general practitioners, the full-time and part-time industrial physicians, and the public health officers, should work together for the benefit of all concerned and for the better promotion of industrial health.

Without attempting to go into detail as to the functions or duties of the general practitioner in relation to industrial health, it may be stated that his chief obligations and opportunities are as follows:

1. To promote industrial health as an important function in the larger field of public health.
2. To maintain joint responsibilities to employers, employes, and official government agencies concerned with industrial health.
3. To recognize and report occupational diseases and all other diseases required by law to be reported.
4. To encourage management and labor to see the value of industrial health conservation.
5. To educate and advise employed persons regarding their health.
6. To make preemployment or preplacement and other physical examinations that may be required and to assist in the follow-up of cases needing correction of impairments.
7. To guide employed individuals to adequate medical, surgical, or specialized treatment facilities where necessary.
8. To assist in matters pertaining to general sanitation of the plant and to have knowledge of the potentially toxic materials or disease-producing processes used in any organization that he may serve.
9. To have a general knowledge of employe and industrial relations and of personnel practices and facilities.

10. To be versed in the handling of traumatic surgical emergencies and in workmen's compensation laws.

11. To work in harmonious and ethical relations with fellow practitioners and industrial physicians.

The most essential requirement for the success of a program in the interest of war-time workers is a sympathetic coöperation between the private practitioners of medicine and surgery, the lay and medical leaders of industry and the various government agencies. It may be stated without much fear of contradiction that the general practitioner of medicine, whether he is giving a small amount of time directly to industrial work or serving industry indirectly as the private physician to employed persons, is potentially the most important unit in industrial health work. On him, at present, largely rests the success or failure of such work, particularly for the smaller industries. While much may be said in favor of the thesis that industrial health service is not a medical monopoly, it must be admitted that it would be more difficult to carry on successful industrial health work without the physician than without the other specialists who make up the so-called industrial health profession.

Industrial Health and the Medical Society

In conformity with the recent trend in several states, it is respectfully suggested that all state medical societies should create standing committees on industrial health and plan the scope of their activities in coöperation with the Council on Industrial Health of the American Medical Association. Moreover, in those counties made up of large industrial populations, the establishment of committees on industrial health in county medical societies should be encouraged. It is here that most of the important industrial health problems and services must be worked out in coöperation with local community agencies, public and private. It is of interest to note that the Minnesota State Medical Association has a Committee on Industrial Hygiene and Occupational Diseases; and the Hennepin County Medical Society, a Committee on Industrial Health. It thus would appear that the medical profession in Minnesota is all set to take its part in the development of a well-rounded industrial health program.

The Council on Industrial Health of the

American Medical Association, created in 1937, has developed a guide to committees on industrial health in state medical societies, which includes the following suggested objectives:

1. To train industry and labor to the value of industrial health conservation.
2. To develop a clear understanding of the proper scope and functions of industrial medicine and to clarify relationships between private and industrial practice.
3. To keep the medical profession informed about all accepted methods for reducing the frequency and severity of industrially induced disability.
4. To elevate medical relations under workmen's compensation.
5. To scrutinize all legislation affecting the health of industrial workers.
6. To improve relationships between medicine and insurance.
7. To establish working relationships with all agencies in the state interested in industrial health.
8. To arrange for the adoption of similar activities through coöperating committees in the medical societies of industrial counties.

To accomplish these objectives it has been recommended by the Council on Industrial Health that the personnel of committees include representation from:

1. Private practice.
2. Industrial medical practice.
3. Medical representation, if such exists, from each of the following:
 - (a) State bureau of industrial hygiene.
 - (b) State workmen's compensation agency.
 - (c) University medical faculties in the state.
 - (d) Industrial insurance companies.

Public Health Relations

Prior to 1936 there were in the United States only five state departments of health and two or three state departments of labor conducting industrial hygiene activities, and even these activities were of limited nature. As of 1942, a total of thirty-six state, four city, two county and two territorial Industrial Hygiene Bureaus have been established, mostly in departments of health. Some of these are of recent creation and have only skeleton organizations. There is great need that these be strengthened as rapidly as possible as a part of our wartime industrial health program. Moreover, additional industrial hygiene units should be organized without delay in the remaining states, territories and local governments, particularly of the larger industrial cities. Many of these recent advances in public

industrial hygiene activities have been due to the leadership of the Division of Industrial Hygiene of the United States Public Health Service, through fundamental research and its application; education; advice on organization; special preparation and loan of personnel and equipment; and technical consultation services.

Somewhat typical of the services rendered by a State Division of Industrial Hygiene are the following, now made available by this Division of the Minnesota State Department of Health:

1. To receive and investigate reports of occupational disease.
2. To promote more adequate medical services within industry, such as the employment of full-time or part-time physicians and nurses, the provision of properly equipped first aid rooms, and the maintenance of sickness records.
3. To encourage the use of ethical preemployment and periodic physical examinations and, as a part of these examinations, the use of the routine serologic test for syphilis.
4. To confer with industrial physicians in regard to special problems or general industrial health programs.
5. To provide on request engineering personnel specially trained and equipped to make studies of plant environment, such as air analysis for toxic vapors, gases, and dust, to determine whether the working atmosphere is safe or otherwise and to make recommendations for the control of health hazards found.
6. To promote adult hygiene programs within industrial groups, such as the control of tuberculosis, syphilis, and other communicable or preventable diseases.
7. To prepare and disseminate information on various toxic materials and processes, and methods for their control.

As noted previously, it is particularly to be hoped that our present war program will result in more active coöperation between industrial medical departments, private practitioners of medicine and local and state Bureaus of Industrial Hygiene. One concrete achievement of such coöordinated efforts might be a much needed national plan for standardized recording and reporting of industrial morbidity and mortality. Moreover, it would be of advantage to all concerned if a plan were developed in each state whereby the plant physician is invited to accompany the official of the state or local Bureau of Industrial Hygiene in his inspection of working conditions in the plant.

Educational Relations

One of the chief unmet needs in connection with the national war emergency, calls not only for more and better undergraduate instruction on industrial health in our medical schools, but also for the organization of short postgraduate courses in strategic training centers throughout the United States. One result of the marked advance in the development of Bureaus of Industrial Hygiene in state and local governments has been an increased demand for trained personnel which it has been difficult to meet. Many war-production industries also are finding it difficult to obtain the services of properly qualified medical personnel.

In a survey which I made in 1934, it was found that only thirteen out of eighty-five medical and public health schools in the United States and Canada gave separate courses on industrial hygiene or industrial medicine. Several medical schools included one or two lectures on this subject in their general course on preventive medicine and public health, while a majority of such schools gave no attention whatever to this important and growing subject. Thus, a wide range of practice in the teaching of industrial health exists at present among the various medical and public health schools. It is natural and reasonable to suppose that those schools associated with universities in the more populous urban and industrial centers will have more demand on the part of students and more adequate facilities for instruction on industrial health than will those located in rural and agricultural parts of the country; the further development of teaching and research on this subject in various institutions naturally must depend largely on such local conditions and requirements.

For those students who expect to become private practitioners of medicine and surgery but who eventually may give part time to industrial health work, it would seem desirable to furnish instruction in medical schools, preferably during the latter part of the course. For those students who expect to take up general public health work on a full-time basis or to specialize in industrial health service, separate courses should be available in graduate schools or schools of public health. For those students or lay business executives who wish to specialize or receive instruction in business or personnel administration, courses on industrial health adapted to the use

of such students should be included in the curricula of university schools of business administration.

Field visits to industrial plants for inspections and surveys should be to the teaching of industrial medicine what hospital ward rounds are to the teaching of clinical medicine. Medical and public health schools which give instruction on this subject should cultivate the friendly co-operation of local industries in order to enhance their facilities for field training of students and research on industrial health.

Where possible, instruction on industrial health, including industrial medicine, industrial sanitation, industrial safety, industrial toxicology and other subjects, should be organized under one separate, independent department with a full-time professor, as coördinator and director, and with the necessary assistants. The head of the department should be a physician with training and experience in industrial health. In the larger universities he might also serve as the director or teacher of courses on this subject not only in the medical school, but also in public health, nursing, business or graduate schools. Detailed subject matter and methods of teaching industrial health must be based on local conditions, facilities and needs. Industrial health, including industrial medicine, will become what physicians and medical educators help the businessman and industrial worker to make it. In this connection, opportunities and responsibilities of educational institutions are unlimited.

Recent Educational Advances

While much remains to be done, some advances have been made in the teaching of industrial health during the past few years. A review made by the Council on Industrial Health of the American Medical Association in 1938 found that fifty-two medical schools reporting, averaged five hours of instruction on industrial health in their four-year curricula. A more recent study shows a further slight increase in the number of hours devoted to this subject. It is hoped that added impetus will be given by (a) the teaching syllabus prepared by the Council on Industrial Health, which has been authorized by the Council on Medical Education and Hospitals of the American Medical Association to take the initiative in such matters, and (b) the recently developed outline on the Teaching of Industrial Health, prepared jointly

by the Council and a Committee of the American Association of Industrial Physicians and Surgeons.

A few medical schools also recently have established short courses on industrial health. These have been organized either independently by the medical schools or in coöperation with local industries, the State Bureau of Industrial Health and other public agencies. One of the outstanding examples of postgraduate education on industrial health is that which was carried on last year through brief regional institutes in several Iowa communities, based on coöperative efforts between the State and County Medical Societies and the State Department of Health.

As of interest in the field of educational relations, was the creation in 1941 of a joint committee made up of representatives of (a) the American Association of Industrial Physicians and Surgeons and (b) the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association to consider and possibly to draw up a plan for certifying industrial practitioners. Based on regulations governing the organization of certifying boards already laid down by the Council on Medical Education and Hospitals of the American Medical Association and the Advisory Board for Medical Specialties, it is hoped that eventually an American Board for Industrial Practice may be created and become operative.

Conclusions

In conclusion, the health and safety of war-time workers and of all workers during the important period of post-war adjustment will depend on the united efforts of (1) the workers themselves, individually and collectively; (2) industrial management and related local, state and national commerce, trade and manufacturers' groups; (3) the medical profession and allied professions of nursing and dentistry; (4) the public health and public safety professions, including official and voluntary administrators, engineers and laboratory specialists; and (5) the educational leaders of the United States.

A few of the fundamental objectives in a co-ordinated local wartime program might be:

1. To stimulate, as rapidly as possible, the evaluation of important hazards to health and safety, particularly in local war-production industries, and to make specific and practical recommendations to the managements for the elimination of any hazards encountered. This is not merely an academic suggestion, for plants holding government contracts must assure the federal government of working conditions "not hazardous or unsanitary, or dangerous to health and safety."
2. To develop community-wide interpretation and local medical education on industrial health.
3. To make provision for at least a minimum medical service in industries having government contracts. Such a service might include (a) physical examinations, (b) a well-organized system of referral for the correction of physical defects to be worked out with the coöperation of the local medical profession and community hospitals, and (c) an adequate system of records and reports.
4. To inaugurate specific contacts with local managements and workers, and to assist in providing medical, nursing, engineering, and laboratory personnel where needed.

In order to implement such a local wartime industrial health program, it is suggested that a joint coördinating committee be set up to include one representative from each of the following groups: (1) employes; (2) organized labor; (3) industrial management; (4) Chamber of Commerce or Manufacturers' Association; (5) County Medical Society; (6) Local Dental Society; (7) Local Nursing Association; (8) Local Health Department; (9) Local Safety Council; and (10) Local Educational Institution. Additional funds or personnel which might be required should be sought from available local, state and federal sources.

Quoting the Federal Security Administrator, "of all health and welfare services, industrial hygiene can make—*must* make—the most direct contribution to winning the war. As in modern warfare, the strategy of industrial health service is teamwork." The State of Minnesota and Hennepin County are to be congratulated on the medical, public health and industrial leadership which they have available to promote active teamwork for the health and safety of war-time workers!

LEGAL ASPECTS OF FIRST AID BY LAY PEOPLE

C. J. POTTHOFF, M.D., Associate Professor of Biological Sciences and
Preventive Medicine, University of Minnesota

and
PAUL CARROLL, Judge, District Court
Minneapolis, Minnesota

IN first aid work, as in medical work otherwise, there is an ever present possibility of encountering legal difficulties. It is estimated that 15,000,000 people will receive first aid training during 1942. Many of these people are assuming posts in Civilian Defense, and are expected to perform first aid in the case of a catastrophe. The possibility of encountering legal difficulties seems to loom as important to them. They wonder about the obligations their positions entail and the risks they assume. Inasmuch as physicians often teach these classes and will in a catastrophe have lay first aiders as assistants, the questions are often directed at them.

The questions most commonly asked by them are considered here. Answers given pertain to first aid in Minnesota, and should not be regarded as necessarily applicable in other states. These answers are not official, but are compiled from sources regarded as highly reliable. These answers are not intended to cover any problems beyond those of strict first aid requirements.

Q. In the case of an accident, is a bystander required by law to render first aid?

This question, so often asked, cannot be accurately answered by a simple statement. There is no Minnesota law at present which specifically requires a casual bystander to render assistance in the case of an accident. But laws have been passed and court decisions have been made which do throw responsibility upon certain people, by virtue of their positions, or because of the circumstances, to render assistance. It is difficult to predict, for many of the hypothetical cases advanced by first aid class members, whether a court might hold that a bystander has a responsibility to help the injured. Let us consider some of the situations wherein there appears to be a responsibility.

A legally qualified physician or nurse employed to render medical or nursing service should under specified or implied terms of a contract render first aid.

A school teacher should, according to various

decisions, care reasonably for a stricken child under the teacher's supervision. She is "acting in the place of the parent." The teacher is not only justified in acting to protect the safety of those entrusted to her care, but she also has responsibilities in acting prudently and reasonably to safeguard these children. The teacher is not only the representative of the parent in the schoolroom, but the courts have also recognized that the teacher has certain jurisdiction over the streets and adjacent property while the child is on the way to or from the school. Though requiring teachers to care "reasonably," the courts have not up to this time demanded that teachers in the mass take formal courses in first aid. It is difficult to state what a jury would regard as reasonable care in any specific case where the teacher is not required to study first aid; but surely she should not let a stricken child lie unattended. No case of this kind appears to have arisen in Minnesota, but it is probable that Minnesota teachers should care reasonably for stricken children.

Inasmuch as bus drivers for Minnesota schools are required to study first aid and to carry some equipment, a jury would probably hold that they likewise must render first aid to children under their control.

The driver of a car which participates in an accident is required to assist injured persons. This is true even though the driver was not responsible for the injury or accident.

What, then, of the obligation of a Civilian Defense worker, trained in first aid? There is at present no specific legislation pertaining to his responsibilities. Nevertheless, it appears dangerous for him to assume that he would not be held, in a test case, to have responsibilities for rendering assistance.

It is anticipated that specific legislation will be passed defining the rights, obligations and duties of all the Civilian Defense workers. Perhaps legislation under the present emergency will throw far more responsibility upon all of us to assist the injured in a catastrophe. New conditions re-

quire new rules, and the law is not unchanging. Certain it is that any person should not be hesitant in doing his best to help the injured. The law and all people look with favor upon those who do humanitarian acts.

Q. Suppose a bystander at the scene of an accident renders assistance. Can he be held liable for injury suffered due to incorrect care given?

A. If the first aider uses reasonable care and judgment, he would not be liable for any injury or damage. But if he performed his acts negligently, he could be held to respond in damages.

What degree of care must he exercise in order not to be negligent? He would probably be required to exercise such care as a reasonably prudent person should exercise, considering all the circumstances such as the injury itself, the entire situation of the emergency, the training of the first aider, etc. It is probable that a jury might expect a higher standard of care from a trained first aider than from an untrained person. It is probable that a physician, giving first aid only and as a volunteer, and though not intending to charge for his services would be held to the same degree of care as if he were treating his own patient. Under ordinary circumstances a doctor is bound to exercise such care, skill, and diligence as is usually exercised by physicians and surgeons in good standing of the same school of practice.

Q. If a person in rendering first aid initiates action resulting in expenses for care, can he under any circumstances be held responsible for the expense payment if the injured person refuses to pay?

A. Yes, the first aider might under certain circumstances be held to have contracted for such service as that of medical or hospital care or ambulance service. Even though the victim gives the first aider permission to undertake procedures involving expense, the latter should explain in advance when ordering service for the victim that he is acting only as a volunteer, and is not otherwise related to nor interested in the party concerned.

Q. Must an accident victim be left lying immediately at the accident scene until authorities such as the police or a coroner have arrived?

A. When the victim is living, the first aider

may at once give him such attention as reasonably seems indicated for the preservation of life or limb. He should of course attempt to gain a clear picture of the whole accident scene and history.

If the victim is dead, the body should not, strictly speaking, be moved. Neither should the possessions on or about the body be moved. When strict adherence to the letter of the law is violated because of the dictates of common sense, the authorities seem to accept the removal as justifiable. Thus it may seem sensible to move a body a few feet from a highway carrying heavy traffic or from a crowded theater-lobby. When a crime is suspected, one should be especially reluctant to move the body.

Q. What is the law pertaining to notification of police authorities in the case of an accident?

A. In all cases in which a crime is suspected, the sheriff or some other police officer should be promptly informed of the facts.

The 1938 Supplement to Mason's Minnesota Statutes of 1927 states: "The driver of a vehicle involved in an accident resulting in injury to or death of any person shall . . . by the quickest means of communication give notice of such accident to the local police department if such accident occurs within a municipality; otherwise he shall in like manner give notice to the office of the sheriff of the county." And further: "The driver of a vehicle involved in an accident resulting in injury to or death of any person or total property damage to an apparent extent of \$50.00 or more shall, within 24 hours, forward a written report of such accident to the commissioner." Special report forms are available usually from local police officers. Accident reports to the highway commissioner should be on report forms, if they are available. It is wise for all to study a blank form in order that they may gather the necessary information should they be involved in an accident.

When a driver collides with and damages an unattended vehicle, he is required to locate and notify the owner or to report the accident to a police officer. If he damages fixtures which are legally on or adjacent to a highway, he is required to take reasonable steps to notify the owner or person who is in charge of the property. A driver involved in a traffic accident is required, in general, to give his name, address, vehicle registration number, and show his driver's li-

cense if requested by the driver of the other vehicle or the owner of damaged property.

Physicians are required to report all cases in which gunshot wounds are treated. Garages and repair shops are required to report to local police and the highway commissioner when incoming motor vehicles give evidence of having been struck by a bullet. Coroners are required to report to the highway commissioner all cases of death resulting from motor vehicle accident.

Q. Under what circumstances should the coroner be notified?

A. The coroner is concerned in certain cases of death. Section 957-2 of Mason's Minnesota Statutes of 1927 provides: "It shall be unlawful for any person other than the coroner to issue a certificate of death in any of the following cases to wit: violent or mysterious death including suspected homicides." Section 946 provides: "Coroners shall hold inquests upon the dead bodies of such persons only as are supposed to have come to their death by violence, and not when the death is believed to have been and was evidently occasioned by casualty." Thus the coroner is allowed some discretion in deciding when inquest shall be held. Coroners appear to interpret the rule above as indicating inquest shall be held if a crime is suspected, but not if the death is accidental, without suspicion of crime. In some localities in the state, local legislation clarifies their duty regarding inquest.

The Attorney General has ruled that in the case of accidental death by drowning, where no crime or violence is suspected: "It is probably best to have a coroner sign death certificate, and in absence of coroner, a private physician called upon finding dead body, could not make a certificate because he was not in attendance at time of death."

The Hennepin County coroner accordingly lists for cases subject to his attention (1) mysterious deaths, (2) accidental deaths, (3) suicides, (4) homicides, and cases where the latter three are suspected. The coroner signs the death certificates in these cases. When doubt exists concerning whether the coroner should be called, he may usually be telephoned and given opportunity to decide whether he should come to the scene of the sudden death. The first aider should be aware that in cases of sudden death it may be necessary to notify the coroner, but ordinarily

decision to call him may be made by others who may be at hand—police, physician. It is difficult even for a physician to decide sometimes, for after all, under what circumstances is a death mysterious or accidental?

Q. Suppose a seriously injured victim refuses an offer of assistance extended by a first aider. Shall assistance be given anyhow?

A. The problem has many aspects. A person, even though mentally competent, may refuse to allow a first aider to splint a fracture. A refusal by a competent person should be respected; otherwise serious legal difficulties may be encountered. It is unlikely that a victim will refuse help if emergency measures for life-saving are necessary, unless the case is that of a would-be suicide. It is legally proper to thwart attempts at suicide.

The difficulty may arise especially with children, disoriented aged, or drunken people. Children may refuse tendered offers of assistance because they fear pain. Judicious handling of the case ordinarily will solve the problem here. If, despite all efforts, the child still refuses an offer to help, in the absence of responsible relatives, the first aider will probably be upheld if he carries out emergency, life-saving measures. He should use caution as indicated for the cases of the disoriented.

Where cases involving first aid for the disoriented are brought into court, the matter becomes a question of fact. The cases may include the drunken, the aged disoriented, the concussion victim, others suffering from a psychosis. Society looks with favor upon those who attempt to relieve suffering and save life. In case of the bombing of a building, when prudence dictates that the building should be evacuated, it may appear necessary to remove such people even against their desires. Jurors would doubtless be very considerate in such cases. No more restraint nor any more treatment should be attempted than is fully justifiable as emergency action. Ordinances will probably be passed defining rights of Civilian Defense workers in this matter. The first aider who exercises due restraint and confines himself to emergency life-saving and limb-conserving measures in the case of a disoriented person who refuses an offer to help will probably not be penalized by a jury. Such court action is unlikely to occur, of course,

and tactful handling of the situation at the accident scene will lessen minimal possibilities of encountering legal difficulties here.

Experience indicates that in addition to questions above considered, students often ask questions pertaining to traffic regulations. It is surprising how few people know the simplest of the traffic regulations, such as those pertaining to parking and to right-of-way. Studies at the University of Minnesota show that less than one per cent of the students tested know what the Minnesota Traffic Code says concerning signaling in traffic. A copy of the Code may be obtained from the State Highway Department. First Aid

classes of course devote attention to accident prevention. Information concerning and stimulation to study the traffic rules has a place in these classes. The informed student has better personal protection. He is better able to get a clear picture of the accident scene when he knows the regulations.

Particular acknowledgment is made for many helpful suggestions from A. J. Lobb, LL.B., of The Mayo Clinic.

THE PREVENTION OF AUTOMOBILE ACCIDENTS

MAURICE N. WALSH, M.D.
Rochester, Minnesota

WE ARE living in the age of preventive medicine. The basic philosophy which underlies more and more of our medical practice of today is that it is far better to prevent a disease than to attempt to treat it after it has occurred. Naturally, this is not always possible, but whenever it can be done it is definitely the duty of the physician to resort to all possible measures to prevent the occurrence and spread of disease and to protect and save human life under all circumstances.

A Neglected Medical Problem

But let us look into the situation in regard to automobile accidents. After an accident has occurred it is the responsibility of the physician to do what he can for the injured person. This is often pitifully little. The number of maimed and crippled minds and bodies seen daily by physicians in this country as the result of automobile accidents is enormous. The death toll of approximately 40,000 lives in 1941 from automobile accidents in the United States is equivalent to the total loss to the country of the entire population of a small city of men, women and children in one year, and certainly far exceeds the mortality from most diseases. Up to the present, however, the physician has concerned

himself very little with the preventive phase of the traffic problem. It may be asked, "Why not leave this to the police?" in whose hands this problem has rested for many years. The answer is that in spite of all the police can do, traffic accidents continue to account for thousands of valuable lives each year and to cause crippling and maiming of many more thousands of persons. Since physicians are entrusted with the responsibility of caring for the patient after the accident, it seems logical that they should have some part in the prevention of these accidents. It must be remembered that physicians are almost the only group remaining in the world today whose sole interest is the saving and protecting of human life.

A Serious Traffic Problem

An impartial review of the traffic problem in this country demonstrates the fact that *something is seriously wrong with the system of traffic control* and it is not difficult to point out what the deficiency is: *we lack a national unified method of traffic control*. Because of this fact evils have multiplied, until today there is no hope of controlling this great problem without the passage of uniform national traffic laws and regulations, effectively enforced. Such measures will make it necessary that periodic medical examination of drivers, compulsory examination of automobiles

From the Section on Neurology, The Mayo Clinic, Rochester, Minnesota.

TABLE I. COMPARISON OF REGULATION OF AVIATION AND AUTOMOBILE TRAFFIC

<i>Aviation</i>	<i>Automobile</i>
1. Uniform national system of laws	Variable local system of laws
2. Enforcement of laws by competent, well-trained national officers	Enforcement of laws by variably trained local officers
3. Careful compulsory periodic medical examination of pilots	No medical examination for drivers' license in most states
4. Careful ground school study, including traffic laws of the air, with compulsory examination for licensure	Traffic schools in relatively few localities with inadequate examination for licensure
5. At least 35 hours of flight training both dual and solo with flight test required for licensure	Usually no driving school or driving test necessary for licensure
6. Compulsory licensure of all aircraft after careful periodic examination	Totally inadequate examination of automobiles, variably enforced
7. Strict enforcement of laws prohibiting flying while pilot is intoxicated	Lax enforcement of laws prohibiting driving while driver is intoxicated
8. Careful planning for future development of air traffic by Civil Aeronautics Board	Lack of any centralized authority for effective future planning
9. No local interference with law enforcement	Much local interference with law enforcement

and trucks, compulsory instruction in traffic laws and in driving, and impartial enforcement of the law by well-trained officers, be carried out.

The Lessons of Air Traffic Regulation

Fortunately, we can turn to aviation for a demonstration of how a national system of traffic regulation can be established. Few people in this country realize what an excellent system of traffic control has been set up for aviation in the United States. Air traffic was not always so well-controlled as it is now. In the barnstorming era, not so many years ago, air traffic was as chaotic as is ground traffic today. Great credit is due the Civil Aeronautics Authority for its excellent work in bringing into being the best system of air traffic control in the world. In the United States so much wisdom has been incorporated into traffic laws of the air that it seems worthwhile to compare them with the condition obtaining in traffic control on the ground (Table I).

Uniform System of Laws.—The greatest advantage which air traffic enjoys is that of a uniform national system of laws embodied in the

Civil Air Regulations.* With minor exceptions, flying is done in the same manner in all parts of this country. In certain areas local conditions require minor modifications of these laws, but as little modification as possible is done. Automobile traffic, on the other hand, suffers from the fatal handicap of being regulated by variable local laws. It is necessary for a driver to travel only a short distance before he reaches an area in which the traffic laws may be very different from those of his own region. The placement of traffic lights, to provide a concrete example, varies markedly from one locality to the next. Consequently, it is easy for the motorist to become confused and to break laws which he never knew existed. In some localities absurd and even ridiculous traffic laws, proper enforcement of which is impossible, are in existence. Too much cannot be said against the dangerous practice of attempting to enforce variable local traffic laws, many of which are unwisely conceived. The advantages of a national system of traffic regulation should be evident to everyone. Enough experience has been gained by studies of traffic to permit institution of a wise system of national laws which could regulate traffic most satisfactorily, with minor local variations as necessary.

Careful Medical Examinations.—To secure any type of license to pilot an airplane, the applicant must pass a careful medical examination designed to demonstrate his physical fitness for handling a high speed machine safely, and this examination must be repeated every six months or every year, depending on the type of license the pilot holds. On the other hand, in most states the person who wishes to obtain a driver's license is not required to undergo a medical examination of any kind, and every physician sees patients who have serious physical handicaps, such as poor vision, epileptiform convulsions, loss of limbs or other serious defects, but who nevertheless drive constantly and frequently are involved in accidents. The question of whether such handicapped persons, who obviously are unfit to operate a motor vehicle, can be allowed to continue to drive automobiles and to endanger population is a most serious one. It is very definitely the duty of the physician to take measures

*Civil Air Regulations, Government Printing Office, Washington, D. C.

to end this danger by demanding the compulsory periodic physical examination of all applicants for drivers' licenses and to insist that this be made a national law, affecting all drivers in the United States.

Enforcement and Personnel.—Traffic laws of the air are enforced by competent, nationally trained officers; that is, by officials of the Civil Aeronautics Board. These men are universally respected and their decisions are so fair and honest that they are rarely protested. They have contributed immeasurably to the increasing safety of aviation and to the saving of human lives. On the other hand, enforcement of traffic laws in automobile traffic is carried out by variously trained local officers. In certain regions, such as large cities, they may be very well-trained indeed. In other areas, however, they often receive no training whatever. At best they are entrusted with the enforcement of many types of laws in addition to traffic laws, and an unnecessary burden is sometimes put upon them by the necessity of attempting to enforce absurd or even harmful local regulations. It is not my intention to disparage the excellent work of traffic control officials in certain parts of this country, where their devotion to duty has resulted in the saving of many human lives. It is simply desired to point out that their efficiency could be increased if one, unified control with a national system of laws were operative.

Technical Qualifications Demanded.—In aviation, careful study of the traffic laws of the air, together with some knowledge of aerodynamics, meteorology and maintenance of airplanes as disclosed by a compulsory written examination, is necessary for licensure of a pilot. In respect to ground traffic, however, schools at which prospective drivers are taught traffic rules exist in relatively few communities and in most places a driver's license can be obtained after a totally inadequate examination. In many states, the payment of a fee is all that is required for the obtaining of a license to drive an automobile, and ignorance of traffic laws is so dangerously widespread in all states that much education will be required before this situation is improved. Yet the necessity for thorough knowledge of traffic laws is very great, since in automobile traffic, as in air traffic, the human error usually is responsi-

ble for accidents rather than structural failure of the vehicle. It cannot be expected that the loss of life from automobile accidents will be reduced unless the driver is required to know thoroughly the traffic laws that he is expected to follow.

To obtain a private airplane pilot's license it is necessary that the students present proof that dual flying (that is, flying with an instructor), together with at least thirty-five hours of solo flight has been carried out. In most courses of instruction, the number of hours of flying with an instructor usually averages about twenty, and a rather difficult flight test (which frequently is failed), conducted by an inspector of the Civil Aeronautics Board, is required for licensure. To obtain a commercial or a transport pilot's license much more experience is required in order to pass the difficult test. In ground traffic, on the other hand, no driving school or driving test usually is necessary for licensure. In a few communities, a driving test is required before a license to drive an automobile can be obtained. Simple observation in any part of this country will convince anyone of the fact that the lack of knowledge of how to drive an automobile properly is widespread. Dangerous methods of driving are so common as to require almost no special mention. Most people do not drive badly because they maliciously disregard laws, but because no one ever taught them how to drive properly. Again, the need is so obvious that no further comment need be made.

Licensure and Inspection of Vehicles.—In aviation traffic compulsory licensure of all aircraft, after careful periodic examination, is required. It is now against the law to fly an unlicensed airplane in any part of this country. Such examination, conducted by inspectors of the Civil Aeronautics Board, has saved countless lives. Structural defects not infrequently are encountered and must be corrected before flying can be done. Experience in aviation has shown that the pilot cannot be trusted to take proper care of his airplane, and consequently, federal inspection was wisely provided for and required. In automobile traffic, on the other hand, there is totally inadequate examination of automobiles, and provisions for such examinations are variably enforced. In most localities there is no inspection whatever. In certain localities periodic inspection of brakes is made, and in certain others various parts of the

vehicle are inspected. Again, the need for a uniform national law requiring strict periodic inspection is evident. There are upon the roads of the United States a large number of automobiles which are totally unfit for driving, and represent dangers to human life.

Personal Restrictions; Evasion of Punishment.

—In air traffic there is strict enforcement of the law prohibiting flying while the pilot is intoxicated with alcohol or with some drug. There are laws prohibiting driving an automobile while the driver is intoxicated, but it is common knowledge that these laws frequently are disregarded and that they are enforced with laxity. It has been well stated that a drunken driver is literally "dynamite on wheels." The effect of even a comparatively small concentration of alcohol in the blood stream is markedly to impair the judgment and efficiency of the driver, and this fact is well established. Could drunken driving be eliminated, the accident rate would immediately decrease sharply. Again it is true that in certain localities strict enforcement of these laws is the rule, but in many localities extremely lax enforcement is common. In aviation there is no local interference with law enforcement, such as so frequently occurs in automobile traffic. The evil of "fixing automobile traffic tickets" unfortunately is widespread. It is common knowledge that federal laws cannot be "fixed," whereas local laws are affected by this evil. Good laws are of no avail if the traffic officer is prohibited from doing his duty by the "fixing" of a traffic ticket.

Planning for the Future.—Finally, the Civil Aeronautics Authority acts as a national agency to plan for the future development of aviation and to regulate air traffic. The high standard which has been reached by civil aviation in the United States is due directly to the wisdom with which this body has performed its function and to the wise leadership of the Honorable Robert Hinckley, assistant secretary of commerce for air. In automobile traffic, on the other hand, there is a lack of any centralized authority for regulation and future planning, and this lack has resulted in many evils. As one example of what may be accomplished in automobile traffic by such a body, I may point out the vital necessity in this country for more two-lane roads, with a small island in the center, to prevent the hazard of head-on collisions which unfortunately are so

TABLE II. RECOMMENDED MEASURES FOR REDUCTION OF AUTOMOBILE ACCIDENTS

1. Uniform national system of traffic laws.
2. Enforcement of laws by competent well-trained officers.
3. Compulsory yearly medical examination for licensure.
4. Traffic school study with examination in traffic laws for licensure.
5. Driving instruction with driving test for licensure.
6. Compulsory periodic examination of all motor vehicles.
7. Strict enforcement of laws prohibiting driving while driver is intoxicated, with severe penalties obligatory.
8. Creation of post of assistant secretary of commerce for ground motor traffic, with a Civil Automobile Authority to plan and direct future development.

common on present highways. Such highways have been built in a few localities, but it is extremely important that many more be established. These roads also would be of great military importance. Close coöperation should obtain between the Civil Aeronautics Board and the group in control of automobile traffic, so that landing strips will be placed along highways and so that certain areas of main highways will run in the direction of the prevailing winds at stated intervals, as has been the case in Germany for several years. A centralized Civil Automobile Authority could carry out many other important measures to aid not only in the saving of lives but also in national defense. An assistant secretary of commerce for automobile traffic, which is certainly of equal importance to air traffic, should be at the head of such a program. In Table II will be found certain recommendations for the improvement of ground traffic control in the United States.

Comment and Conclusions

We cannot do better than to follow the lead which aviation has so well set. Better traffic control is imperative and is the only method by which the number of automobile accidents can be reduced. Appeals to sentiment will reach only those persons who in most cases are already exercising due caution in driving. They will not reach those who are responsible for most accidents. Experience has shown that appeals to sentiment cannot be relied on to save human

lives. *There is no substitute for wise regulation and efficient law enforcement.* It need not be feared that liberty would be lost by this method and it cannot be denied that many lives would be saved thereby. The difficulty of establishing a national system of laws is very great, but the difficulty need not deter us. In a time of national emergency, when every life is valuable to our country it is the responsibility of physicians to take the steps necessary to secure those measures which will result in diminishing the enormous death rate from automobile accidents. We no

longer can afford to be careless of the lives of our citizens. The recommendation by medical societies and other organizations of some such national system of laws, as has been mentioned herein, would carry great weight and this is the only method by which this can be accomplished. It is our duty then as physicians to demand that a national system of laws be quickly framed and adopted, in order that the lives of thousands of our fellow citizens may be safeguarded, and that mutilation and death from avoidable automobile accidents be eliminated.

MECHANISM OF UVEITIS

ERLING W. HANSEN, M.D.
Minneapolis, Minnesota

DURING the past quarter of a century the etiology and method of development of inflammations of the uveal tract have interested many observers and our understanding of the nature of uveitis has been greatly enlarged. It is less than thirty years since Billings emphasized the importance of focal infections in eye diseases. The following year, 1913, the section on Ophthalmology of the International Medical Congress in London discussed the "Pathogenesis of Chronic Uveitis, Excluding Syphilitic, Tuberculous and Sympathetic Cases." De Schweinitz at that time gave it as his opinion that every case of uveitis is of septic or toxic origin. There was an awakened interest in the subject and among others, Rosenow, in 1915,¹⁰ and Irons and Brown, in 1916,⁸ reported valuable experimental work on streptococcal infections. Benedict¹ with Rosenow² and some of his co-workers contributed valuable experimental and clinical evidence. Alan Woods¹⁷ and his associates have done a tremendous amount of work on all phases of the problem.

It is interesting to note that in the older textbooks, syphilis is given as the major cause of uveal inflammations. In Vienna and some of the other German schools, it has been taught for some time that the predominant cause is tuberculosis. In our own country and in England, focal infection has been accepted as the underlying cause of most cases. Older theories of auto-intoxi-

cation, menstrual disturbances *per se*, and some other toxemias, except as they affect the general health and resistance, have been pretty generally discarded.

The causation of some forms of uveitis is so relatively evident that it is not necessary to discuss it in detail. We refer first to injuries in which infection is carried into the eye from without, excepting the development of sympathetic ophthalmia, which we will discuss later. Also there are those patent cases of septic choroiditis, endophthalmitis occurring with a general septicemia, or with severe systemic infection occasionally seen in acute exanthematous diseases. Lastly, we have those cases in which there is a patent tubercle in the choroid or iris, or a syphilitic nodule, both of which quite evidently come from deposit of the infecting organism carried in the blood.

In an earlier paper⁷ we tried to convince ourselves that there were some distinguishing characteristics of iritis caused by various etiological factors. The more cases that one sees, the more one is convinced that clinically it is difficult, if not impossible, to differentiate. We are speaking now of the general run of acute and/or recurrent cases of uveitis. There is a marked similarity clinically in cases where the etiological factors may be widely divergent. This naturally brings up the question of how infection with syphilis, tuberculosis, gonorrhea or from such isolated foci

¹Presidential address delivered before the Minnesota Academy of Ophthalmology and Otolaryngology, October 10, 1941.

as peri-dental tissues, tonsils, prostate, cervix, etc., or other remote factors cause this picture.

Duke-Elder⁵ says:

... Inflammatory lesion in the eye could be excited in one of three ways.

1. By direct organismal infection, the micro-organism being liberated into the bloodstream and finding lodgment in the eye.

2. By systemic intoxication, the toxins derived from micro-organisms (either exotoxins, liberated by bacteria, or endotoxins released by autolysis of dead micro-organisms) finding their way to the eye by the bloodstream.

3. An allergic sensitization may occur, due to the liberation of foreign protein at the site of infection, the proteins in question being derived from the invading organism itself or elaborated in the reaction between it and the infected tissues.

That there is actual invasion of the uveal tissues by infecting organisms carried in the blood, we may not doubt. The experimental work already spoken of and much more of which nothing may be said here, has proven this conclusively. There are, however, many times as many people who have infections in whom no uveitis develops, as there are those who have it. Rosenow¹¹ spent much time in the study of selective action of bacteria for certain tissues. This elective localization was shown to be true in the case of experimental animals, using infective material from patients in whom iritis was present. It seemed that both culturally and experimentally the organisms tended to grow in media or in tissues where the oxygen tension was similar to that in the case from which the organisms were derived. Many bacteriologists and pathologists have failed to agree with Rosenow on his theory. The fact remains that organisms were recovered from experimental animals with iritis and the process repeated from animal to animal.

In addition to bacterial invasion viruses in herpes, both simplex and zoster, apparently can produce uveal inflammation. A specially virulent form of uveitis, Harada's disease, presumably is caused by a virus. In 1937⁶ Jonas Friedenwald reported a severe case of bilateral uveitis, retinitis, and optic neuritis in a young woman in whom careful study did not reveal any of the usual etiological factors. Subsequent animal inoculation of spinal fluid from the patient revealed a filter passing agent which produced lesions in the eyes of rabbits, dogs and cats, which were similar to those of the original case. Mice seemed to be re-

sistant to the infection and rats and guinea pigs showed relatively minor reactions. This is only one case, but knowing the caliber of the observer, and noting the extremely complete study of the case and the thoroughness of the animal experimentation, it seems only logical to conclude that in addition to micro-organisms, filterable viruses can also cause severe eye inflammations, endogenously.

With respect to Duke-Elder's second group, Alan Woods,¹⁶ following up the earlier work done by Guillery in Germany on ferment-producing bacteria, produced uveitis experimentally with products of cultures from *B. prodigiosus*. Guillery and Woods' work was done by intravenous injection. Brown³ injected intra-ocularly streptococcus toxin with resultant uveitis. Of the more recent reports Siniscal,¹³ working with material from dental foci, was not able to produce uveitis in rabbits, by introduction of the toxins from culture of this mixed bacterial group, while he could from the organisms themselves, both on intra-ocular and intravenous injection. The toxins were not introduced intra-ocularly.

Direct invasion certainly occurs in a percentage of cases of uveitis, whether it be bacteria, filterable virus or toxic products of bacteria. This undoubtedly accounts for some of the acute cases. When we consider the much larger number of patients, with infections known to produce uveitis, we may well wonder why more people do not develop trouble. Immune reactions undoubtedly account for many eyes being saved. We may well ask ourselves, however, why, except for the purulent endophthalmitis sometimes seen with overwhelming infections, we do not see more of the common run of uveal involvement in these cases?

Few eye complications develop in frank cases of pulmonary tuberculosis. They are much more often seen in healed patients, and more especially where hilus glands are about the only demonstrable evidence of infection, aside from positive skin tests. Acute iridocyclitis is seldom seen in acute specific urethritis; much more commonly in chronic urethritis or prostatitis. Experimental studies made by Swift and Derrick⁴ and by Schultz and Swift¹² have shown that the tissues of the eye could be sensitized more readily by repeated small inoculations or better yet by leaving an agar implant in the tissues, than by large injections of infecting agents.

There must be another factor which enters into the mechanism of uveitis. In the present state of our knowledge this seems to be the third factor of which Duke-Elder speaks, namely tissue sensitivity by whatever name we wish to call it. While immunity saves, her evil half-sister, allergy, destroys. There has been a great deal of experimental work, in addition to that already mentioned, which has proven that almost all tissues in the eye can be sensitized to foreign substances, from serum to bacteria of various kinds and their products. The initial reactions are seldom severe without subsequent injection, either in the eye or systemically may set up violent reaction in the tissues. An interesting and instructive case which parallels some of the experimental work was reported in 1939 by Muncaster and Allen.⁹ The patient, a teacher, aged thirty-one, was given a routine tuberculin test. There was no positive skin reaction to the initial small dose. A second larger dose gave a strongly positive reaction, as well as lighting up the first area. First the left eye, followed in a few hours by the right, developed classical symptoms of irido-cyclitis, edematous corneas, cloudy vitreous and, what was seen later, after the media cleared, round spots of grey exudate near the disc in each eye.

Another very interesting case is that of Theodore and Lewson,¹⁴ which parallels some of the experimental work done with foreign sera. The patient, a man, aged forty, developed bilateral iritis together with other classical symptoms of serum sickness, after being given four doses of type I antipneumococcus serum. There was only slight pain, moderate circumcorneal injection, but much heavy fluffy white exudate in the anterior chamber and over the posterior corneal surface. Clearing was rapid; no chorioidal foci could be seen after recovery, which was complete.

These are to me striking examples of what we have been talking about, the sensitization of uveal tissue, which may not be of great importance in respect to treatment in the present light of our knowledge, but a better understanding of the processes with which we are dealing eventually brings a better mode of attack. Incidentally, the question of sensitization of ocular tissues may become very important from a medico-legal standpoint and actually have twice in our own practice, within the past year, one a case of recurrent iritis resulting in Iris Bombé and secondary

glaucoma, and the other, parenchymatous keratitis.

One of the severest forms of uveitis, sometimes called malignant uveitis, is the type that has been designated sympathetic ophthalmia. From Elschnig's work on uveal pigment which he showed could act as an antigen and which could produce an anaphylaxis in the species from which it was derived or in a different species of animal, came his theory of an allergic basis for sympathetic ophthalmitis. Woods¹⁷ confirmed Elschnig's work, and added much more valuable information experimentally and clinically. He found a positive complement fixation test to uveal pigment in patients who had suffered injury to the uveal tract and had healed without sympathetic inflammation. This was absent in those who developed sympathetic ophthalmia or protracted inflammations. Intradermal tests were positive in the sympathetic cases and negative in normal individuals and some with other eye inflammations. Friedenwald has done more work on the pathologic phase of this condition and while the whole picture is still not quite clear, it, also, is coming clearer.

Endophthalmitis phaco-anaphylactica is the name given by Verhoeff to the severe inflammations in the eye from lens substance. These occur in some individuals where lens substance has been left in the eye at operation for cataract or in needling operations, especially the second eye. Uhlenhuth had shown that lens protein was organ specific, and Verhoeff and Lemoine¹⁵ found that these cases had a positive reaction to intradermal injection of lens antigen, another evidence of allergic reaction in the eye.

Summary

1. Uveitis is due to actual invasion of organisms as evidenced by development of tubercles in the chorioid, ciliary body and iris, syphilitic nodules, or in free pus formation in septicemia, et cetera. Filterable viruses probably also set up direct inflammation of uveal tissue.

2. There is possibly involvement by endo- or exotoxins produced by bacteria, causing direct irritation.

3. Probably most important is the production of a hypersensitivity of uveal tissue to allergens of various types, whether of virus, bacterial proteins, uveal pigment, lens substance and/or other proteins.

NASAL SINUSITIS AND ORTHOSTATIC ALBUMINURIA IN CHILDHOOD

W. RAY SHANNON, M.D.
Saint Paul, Minnesota

ORTHOSTATIC or postural albuminuria constitutes one of the enigmas among the many that are encountered by the physician caring for children. It is my purpose to record a rather interesting feature of this disease which I have recently observed.

The outstanding feature of this condition is the appearance of albumin in the urine when the subject is standing up, the urine being albumin-free when he is lying down. This characteristic must be supported by the total lack of evidence aside from the albuminuria, suggesting kidney disease, such as elevated blood pressure, pathological microscopic elements, etc. Some observers permit the presence of a few casts and red blood cells without removing the case from this benign class.² It seems doubtful that such laxity is wise.

An attempt has been made by certain writers to give greater definition to albuminuria of this type by adding other specifications. Some think that lordosis, leading to circulatory back pressure on the kidneys, is responsible.⁴ They have considerable support for their opinion in that conditions artificially imposed to simulate lordosis while the patient is prone may result in the appearance of albumin in the urine, and in that vice versa, the assumption of a posture which eliminates lordosis while standing may result in its disappearance.³

Other investigators have successfully enlarged

upon the passive congestion theory by showing, through the medium of ureteral catheterization, that it is the left kidney from which the albumin comes, back pressure being greater on this side because of impingement upon the left renal vein by the aorta.¹ Still other writers made note of the importance of infection.⁵

Regardless of minor points, agreement seems to exist among most observers that it is benign in character, that it occurs most frequently in children and young adults, and that it tends to disappear with increasing age. At the same time it becomes very evident that the burden of proof as to the harmlessness of such albuminuria rests heavily with the physician making the diagnosis.

For many years I have been aware of the fact that there is a very close connection between infection of the nasal sinuses and disassociated albuminuria. The relationship is so intimate that experience has led me to suspect nasal sinusitis in any case showing albumin without other discoverable evidence of kidney disease. In the course of observation of a case of this type I became aware that it was only the daytime urine that contained albumin. Urines collected before getting out of bed in the morning were invariably albumin-free. This discovery led to like investigation of other cases and it soon became evident that such was the usual thing for this type of case. The following instances are typical.

Case 1.—A boy, fourteen years of age, complained of abdominal pains arising, as subsequent events showed, from an irritable colon. In the course of his examination a heavy cloud of albumin was found in his urine. Microscopic examination was negative. At his second visit, five days later, it was found that the urine passed before getting out of bed in the morning was free of albumin while that obtained at the office showed a light cloud. The relationship of this situation to nasal sinusitis was recalled, but since he had no complaints and there were no evident findings pointing toward that condition, nothing was done. A week later, early morning, day, and evening specimens were all albumin-free.

However at this time he developed a "cold" followed by obvious nasal sinusitis. The next urinary samples, examined one week later, showed the early morning sample to be albumin-free while that obtained at the office contained a heavy cloud of albumin. A large amount of muco-pus was removed from the nose by nasal suction. The next pair of urine samples was examined four days later, and both samples contained albumin in large amount. On close questioning the patient admitted that he had forgotten to obtain the morning sample until he had been up for fifteen minutes. The same thing happened once again at a later date.

Under continued treatment the nasal sinusitis cleared so that at the end of six weeks the patient seemed to have recovered. During this time early morning samples of urine remained albumin-free while those obtained at night or during his office visits contained albumin in amounts decreasing until it finally disappeared.

A week later, while the morning urine was still clear, a faint trace of albumin was found to be present in the daytime specimen. The patient said that he had had a slight "cold" during that week. Since then the patient has been well of evident nasal infection and the urines have remained free of albumin both day and night.

During the period of observation no pathological microscopic elements were ever found. The blood pressure on one occasion was 108/65. The x-ray confirmed the clinical diagnosis of nasal sinusitis, locating the pathology in the maxillary and ethmoidal sinuses.

Case 2.—A boy, twelve years of age, was brought to the office because of general disability and constant "colds." Violent infection of the nasal sinuses was found to exist. The urine contained a heavy cloud of albumin but no microscopic finding. Subsequent tests showed the urine taken before arising in the morning to be albumin-free, while that taken at night or during the day contained varying amounts.

Under treatment, evidence of nasal sinusitis gradually lessened, and the amount of albumin in daytime samples gradually diminished until both finally disappeared in about one month. On two later occasions, separated by rather long intervals, both morning and evening samples of urine were found to be albumin-free. Improvement in the boy's general condition had paralleled that of the sinus infection and at the time of the last urine examination he was reported to be well.

Case 3.—A girl, seven and a half years of age, was brought to the office because she was constantly clearing her throat. She had had two "colds" in the preceding two months. She was found to have a low grade nasal sinusitis. Her urine contained a heavy cloud of albumin with no microscopic findings. Urine taken the next morning before she had gotten out of bed was free of albumin. Ten days later another comparison of morning and evening samples revealed the morning sample was still albumin-free while that taken at the end of the day contained a heavy cloud. The comparison was repeated later, at a time when the sinus infection had apparently cleared, and both samples were free of albumin.

These examples typify my general experience. The children have not been lordotic individuals, and it would seem doubtful from the physical types represented that such a factor was basically significant. Even though it might have been, its ultimate importance must have been secondary since the albuminuria cleared without attention to posture.

A similar position must be taken in attempting to apply Rytand's observations.⁶ His subjects were apparently adults. This of itself introduces a conditioning element which might even exclude all of the cases that I have seen, since according to general opinion most individuals exhibiting real orthostatic albuminuria would have recovered spontaneously before reaching adult life. The relatively high percentage of anatomical abnormalities that presumably contributed in his cases would seem to make it clear that whatever conclusions he could have made would have to be revised and accorded at most an outside chance of important consideration in cases such as I have described.

The one finding common to all has been nasal sinusitis. As would be expected this has led to a periodic character of the albuminuria depending on the state of activity of the sinusitis. Russell was inclined to assign considerable importance to infection in relation to postural albuminuria.⁶ However, he made no mention of focal infection though he did describe many of the symptoms of nasal sinusitis in his cases. For instance, it was quite common following scarlet fever, and his patients were often sickly, and had frequent headaches, etc.

It is impossible for me to take the cheerful view regarding the prognosis that seems to be held by a majority of the observers. I have

no idea what actually causes the kidney to be permeable to proteins at these times, but I do know that in my cases the agent that accomplished that end result is associated with infection and that it therefore is probably harmful. Furthermore, I have seen too many serious kidney lesions resulting from nasal sinusitis to view without concern any albuminuria associated with that condition regardless of whether microscopic elements were present or not.

Whether other focal infection than nasal sinusitis ever stands in this same relation to orthostatic albuminuria or not I do not know. One should expect that it would be true but my experience does not allow any conclusion on that point. Also it is not my intention to imply that all orthostatic albuminuria is related to focal infection.

Summary

Attention is called to the fact that orthostatic albuminuria in children is a frequent accompaniment and apparently a result of nasal sinusitis, especially of a subacute or chronic type.

Such being the case it is contended that orthostatic albuminuria must be viewed with much more concern than has been the custom in the past.

MEDICO-LEGAL AND SOCIOLOGIC ASPECTS OF DIABETES MELLITUS

ARCHIE H. BEARD, M.D.

Minneapolis, Minnesota

and

JOHN A. LAYNE, M.D.

Great Falls, Montana

DURING the past few years various individuals have suggested that the diabetic patients may be controlled satisfactorily without the use of blood sugar determinations. They have advocated only the examination for urinary sugar. This concept admits of the greatest concern for the diabetic patient who has hyperglycemia. The patient who has no glycosuria, but who may be having periods of hypoglycemia has been forgotten in our enthusiasm to control glycosuria at all times. The diabetic patient who has persistent glycosuria injures chiefly himself, while the patient suffering from hypoglycemia may become a menace to other individuals. We are inclined to doubt the wisdom of any régime which does not stress the dangers of hypoglycemia as much as those of hyperglycemia.

It is well known that the level of the blood sugar at which symptoms of hypoglycemia appear varies among individuals. There is also a variation in the same individual at different times, and the level at which symptoms appear in

children is, as a rule, lower than in adults. It must be remembered the rate of fall of the blood sugar is an important factor in determining the level at which symptoms occur. This seems to be responsible for the difference in the symptoms of overdosage from regular insulin as contrasted with protamine zinc insulin. The diversity and lack of association of premonitory symptoms which occur in hypoglycemia as a result of overdosage of protamine insulin, often result in a state of chronic hypoglycemia. As a result the patient may later disclaim all knowledge of many acts which he may have done.

It is probable that every diabetic patient taking insulin sooner or later develops symptoms of hypoglycemia. If the patient learns to recognize the earliest premonitory symptoms produced from over-dosage of regular insulin, he is able to stop the reaction before it progresses further. This is not always true with protamine zinc insulin and before he realizes his condition his ability to make decisions may be lost.

We have been told, especially when using protamine zinc insulin, that headache, nausea, vomiting and vertigo are the symptoms which the pa-

These findings were accumulated from private practice and the Diabetic Clinic of the University Hospital at the University of Minnesota. This paper was presented at Minneapolis, Minnesota, May 9, 1941 before the Minnesota Society of Internal Medicine.

tient may associate with this condition. These symptoms may not always occur and the patient is unable to realize his condition before periods of disorientation, aphasia, and mental confusion develop. Therefore, the patient may continue to work automatically and it may be difficult for an observer to realize that a hypoglycemic reaction is present.

The slowness in the fall of the blood sugar is thought to be the explanation for the lack of premonitory symptoms and the cause for the suddenness of a hypoglycemia reaction as it sometimes occurs with protamine insulin. It is also well recognized that the action of protamine insulin is prolonged for more than twenty-four hours. As a result there may be a continuous state of mild hypoglycemia when the next daily injection is taken. We must note that any regulated diabetic under good control is subject to reactions because of both intrinsic and extrinsic variations beyond his control. Any number of

slight changes in his environment may occur in his daily routine, as increased muscular exercise, or a meal that has been delayed or omitted. An unusual day at the office or heavy emotional strain, excessive exercise, such as volleyball late in the afternoon, or even an unusually prolonged evening of dancing, may upset the daily slight rise or fall of the blood sugar. At times a gastrointestinal affection which impairs the absorption of food may be sufficient to provoke a hypoglycemic episode in a previously well-controlled diabetic. The presence of sugar in a fasting, a postprandial or in a twenty-four hour specimen of urine cannot be depended upon to insure against hypoglycemia, since there may occur only a transient glycosuria. Sindoni has shown that no apparent quantitative relationship exists between the blood sugar in diabetic individuals receiving, either alone or in combination, protamine zinc insulin and ordinary insulin. He has pointed out, moreover, that the quantitative increase of dex-

trose in the urine after breakfast may alarm the physician into thinking that the patient has a markedly elevated blood sugar, whereas, only a relatively mild and transient elevation actually occurred. Finally, hypoglycemia from the use of protamine zinc insulin may be prolonged beyond twenty-fours, until an accumulative effect results in a severe reaction. One must always remember the severity of the reaction from protamine zinc insulin may be due to prolonged release of insulin from the site of repeated injections. As a result, permanent cerebral damage develops and a continuous low blood sugar over a period of days leaves the patient unable to interpret his difficulties. The public may think he is peculiar, but not realize the cause.

The patient has been taught to expect certain physical change as the symptoms of an impending reaction. They are principally, palpitation, and sweating with regular insulin, and nausea, vomiting and headache with protamine insulin. We next tell them asthenia develops in a later stage of both conditions. These statements are all very true, but we rarely impress upon the patient's family the necessity of watching for other

bizarre symptoms. There are the neurological phenomena that occur with hypoglycemia. Vertigo and diplopia may be understood by the patient but tremor and ataxia, which the patient's family or the public may observe, is such a late manifestation that he may not be able to interpret them. This is followed by paresthesia, aphasia, twitchings and rigor and later by weakness or paralysis in one limb or group of muscles. One patient demonstrated this so completely that it was thought she must have developed a cerebral hemorrhage. We have been lead to believe that a reaction is demonstrated by a polysymptomatic condition, forgetting that monosymptomatic manifestations may occur. Monosymptomatic seizure may be shown only by the development of a tic.

All the above manifestations are only neurological and again we must turn to mental changes for expression of hypoglycemia. Here again the symptoms may occur alone and the usual findings expected and discussed above may not appear. It is for that reason we have to be so careful in evaluating our findings before any definite decision is made. There may, at times, appear signs of irritability, anxiety, depression or excitability.

These are all conditions which occur in so-called ordinary individuals. Therefore, it must be recognized that hypoglycemia brings many sociological and medico-legal aspects.

There may be only a partial disorientation and confusion, with a tendency to loiter and slowness of thought and action. At these times the patient is not able to comprehend his condition. It is, therefore, very important that some member of the family recognize what a condition of irritability, excitability, or hilarity may demonstrate. At times some diabetics become morose and sullen and apparently very embittered with people around them. One wife told us at times her husband, without apparent cause, refused to sit at the table with her and engage in conversation. He stated later he could not remember the instance.

These patients, at times, have been known to isolate themselves in some other part of the house. Others, who are usually considerate, have become very rude. One patient, whose dinner was delayed one-half hour as a result of the late arrival of guests, met them with a rather blunt welcome. At another time this same individual, when taking his family to a public dining room became

very abusive to the management when he was delayed in getting his table as previously arranged. The next day his son remarked to him that he could not treat the public and his family as he had the previous evening. He was surprised and was not able to remember any of the conversation.

Some will not be able to think rapidly enough to forestall an automobile accident, and others are incapable of handling various types of machinery, depending on their occupation. One of our patients was seized with a hypoglycemic reaction while driving from the city to his home, late in the evening. His only remembrance was his one thought to drive through traffic as fast as possible. Fortunately, no accident occurred. He was greatly surprised, upon returning to consciousness at home, to find his wife giving him orange juice and crying about his condition. Stenographers have been known to sit at their machines and cry, not able to operate them or understand the cause of their trouble. Individuals running machinery, such as seamstresses, locomotive engineers, et cetera, should be warned of the possible danger to themselves and the pub-

lic. One individual who was promoted from fireman to railroad engineer refused his new position for this reason. He stated to me, the railroad for which he worked had never been able to find glycosuria during his yearly examination. He attributed this to the extreme care he and his wife took to keep his urine sugar free. These patients may be unable, during their reactions to make the simplest decisions and at times have been unable to take food or sugar which they might carry with them for such an emergency. One patient during a reaction while shopping downtown was able to decide that she needed candy and went to the confectionery store, but after arriving was unable to ask for it. At other times they have been known to misname the object they desire. Other patients have been known to be very abusive and scold their family and friends. Children have become problems to parents and teachers because of their misbehavior late in the mornings and afternoon towards the end of the school periods. Earlier in the day they have been different individuals and the most coöperating and brilliant students.

As a result these abnormal behaviors gradually

exclude a diabetic from social contact with the world and their family. At times, business associates misunderstand their remarks and it may mean their success hinges on a condition that even the doctor has not understood or explained to the patient and family. Estrangement between husband and wife has been known to occur. Because of his anger a husband beat and injured his wife. One patient was ashamed to find later that he had blackened his wife's eye. We have all been led to believe that these patients usually develop asthenia early but apparently this may be a later manifestation and may occur after some mental abnormality.

At times a diabetic may develop increased difficulties in speech, thought and action. Sudden pseudo-hysteria, negativism, psychomotor hyperactivity have occurred. It may manifest itself by maniacal behavior and acts of violence. Exhibitionism, sexual perversity, compulsive laughter and crying occur. Impulsive actions may be followed by later increasing disorientation and confusion. Other individuals have developed delusions condemning their friends, family and business associates. Hallucinations and wander-

Gradually over two weeks symptoms of headache and other disturbances disappeared. Paralysis of face and arm improved. At present is unable to remember dates or to call articles and individuals by their proper names. This condition has never entirely disappeared.

ings may appear. One such young man was found wandering within two blocks of his home unable to tell where he lived and because of his mental condition and ataxia was placed in jail by an officer of the law. Only the fact that some of his boy friends reported his difficulty to his mother, who immediately telephoned instructions to the police station, saved him from serious and prolonged hypoglycemia. Within a few minutes after taking some sugar, he was able to tell his name and home address. The last event he could recall was playing baseball on a vacant lot. Because of the ataxia, confusion, abusive language, and attempts to hit people these individuals may be picked up on the street and thought to be intoxicated.

Melancholia and paranoia occur at times. In some instances they have even been placed in hospitals as insane until the trouble is recognized by an intelligent physician. At times their actions have directed them to break dishes and furniture in public or at home. One such individual entered the University Hospital during the last year. He had tried to commit suicide on three occasions. Not until his hypoglycemia was discovered and corrected did his melancholia disappear. This basis for defense in a few instances, when an individual has killed another person, stating later he was not responsible for his actions, has been recognized by the court.

It has been reported at times the release of inhibitions from moral, religious, and educational restraints have been expressed by pathological state in which various sexual reactions have occurred. One man stated to us that he was very ashamed he had abused his wife. His embarrassment on finding he had attempted to hit her

while in bed was only substantiated by the fact that he had destroyed the plaster on the wall next to his bed where his wife stated he had driven his fist while attempting to hit her. Nocturnal maniacal episodes have been followed by calling the police when the family or public have not recognized the cause.

There is also a certain aspect of civil law which must be considered. Wills and other legal documents drawn up when the party is in a hypoglycemia reaction may be contested. One of us has insisted in two cases when large wills were being signed to have blood sugar determinations at the same time to protect the testator's wishes. Civil suits for libel and slander against diabetics should take into account the possibility of hypoglycemia. Divorce and breach of promise suits should be considered with this view in mind. There are presented in the following charts various cases in which blood sugar determinations were completed during peculiar sociological reactions. It is interesting to review the blood sugar reports.

In conclusion, it is our belief that insulin, and protamine zinc insulin in particular, should be used with a great deal of care. It is our opinion, that injections of protamine insulin greater than forty units a day are not advisable and frequently are dangerous. Urinary sugar should not be depended upon, if peculiar mental conditions are occurring. The patient's urine should not be continuously sugar free. Blood sugar determinations should be made at periodic intervals even when there is no urinary sugar. As much, if not greater care should be extended in monthly supervision of a diabetic taking insulin who shows little or no glycosuria throughout the day,

as the patient who is showing large amounts of sugar in the urine. His family should be acquainted with the fact that mental changes may occur in hypoglycemia and today the family should be trained as well as the patient in these phases of diabetic therapy. However, we do think we should impress upon the patient and family that these conditions only rarely occur and are not the usual results if care in therapy is used. We do wish to bring the facts presented

here, as well as our findings in the charts, to the attention of the doctor. At a rule, he has not been conscious of this phase in insulin therapy, especially if using protamine insulin in large amounts.

HISTAMINASE IN THE TREATMENT OF URTICARIA AND OTHER DERMATOSES

CARL W. LAYMON, M.D.
Minneapolis, Minnesota

IN 1939, Cumming and I⁷ reported seventeen cases of urticaria, two of dermatographism, and eight of atopic dermatitis, which were treated with histaminase. The results are summarized in Tables I, II and III.

Since the number of our cases was so small, we were unable to draw definite conclusions concerning the value of the drug in the treatment of the dermatoses mentioned, although we believed that histaminase was a useful adjunct to the treatment of urticaria, since our cases were of relatively long duration and had, in most instances, proved refractory to the usual therapeutic measures.

Although numerous reports concerning the use of histaminase in the treatment of various allergic diseases have appeared since our publication, those of Knoll and Beinhauer,⁶ Forman,³ Baker,² Altose,¹ and Goldberg⁵ are of special interest to the dermatologist. After thorough study, Knoll and Beinhauer concluded that the syndrome of anaphylaxis in guinea pigs was unaffected by pre-treatment with histaminase, and that intracutaneous wheals produced by histamine in normal, as well as allergic persons, were not altered by the previous administration of histaminase. The clinical effect of the drug in patients treated by Knoll and Beinhauer is summarized in Table IV.

The authors noted that more than one-half of the patients who were decidedly improved were

TABLE I. URTICARIA—SEVENTEEN CASES

Clinically cured	10	(59%)	In the cured cases the duration of treatment varies from 4 days to 3 weeks. Average time for cure 10.7 days.
Improved	2	(12%)	One patient had urticaria for 9 months and was 50 per cent improved in 3 weeks. The second patient had urticaria for several years, and was 90 per cent improved after 2 months' treatment.
Unimproved	5	(29%)	In the unimproved cases the durations were: 1, several weeks; 2, several weeks; 3, five months; 4, two years; 5, three and a half years.

TABLE II. URTICARIA FACTITIA
2 cases

No benefit in either case. One treated three weeks, the other six weeks.

TABLE III. ATOPIC DERMATITIS
8 cases

No definite improvement in any. One month's trial of histaminase given, either without local therapy or without change in local therapy in use at the time of institution of histaminase.

affected with atopic dermatitis or acute urticaria, two diseases given to spontaneous regression or even complete involution. The results with acne vulgaris were practically negative. The toxic effects from histaminase were negligible.

Forman, in January, 1940, reported a study of

Pruritus ani	2	0	0	2
Total	33	4	3	26
Grand total	134	35	14	85

twenty-nine cases. He gained the impression that histaminase offered a new and helpful approach to the treatment of urticaria, angioneurotic edema, atopic dermatitis, and allergic coryza. His results in contact dermatitis and asthma were much less satisfactory. No untoward side effects were noted except in one case of urticaria in which the drug seemed to aggravate the condition and cause nausea and hyperacidity. He felt that no final conclusions could be reached without further studies.

Baker, in 1940, reported the successful treatment of two patients with hypersensitiveness to cold by the combined use of histaminase and a method of systemic desensitization to cold (immersion of the hands in ice water for gradually increasing periods). Baker also cited the excellent results obtained by Foshay and Hagebusch⁴ in the treatment of serum sickness and the use of the drug by Roth and Ryneerson⁸ in the treatment of insulin reactions.

Altose treated eighteen cases with histaminase, including seven of urticaria, four of angioneurotic edema, three of both combined, and four of allergic dermatitis. In 44.4 per cent great im-

provement was obtained, in 33.3 per cent moderate improvement, and no change in 22.2 per cent. Results in the various types are shown in Table V.

TABLE V

	Greatly improved	Moderately improved	Un-improved
Urticaria only	4	3	
Angioneurotic edema	4		
Both		2	1
Allergic dermatitis		1	3

Altose stated that several of his patients who were being treated with histaminase were able to freely eat foods which had previously caused immediate urticaria. He added, however, that the fact that all of his cases of acute urticaria were relieved did not prove the efficacy of the drug, since urticaria is a capricious disease, and often terminates spontaneously. In his opinion, histaminase proved of definite value in chronic urticaria.

Goldberg, also in 1940, reported the results in dermatoses treated by histaminase orally, shown in Table VI.

TABLE VI

Diagnosis	No. of cases	Results	Comment
Papular urticaria	1	Cured	Histaminase alone
Atopic dermatitis	3	Improved	Histaminase plus other therapy
Dermographism	2	Unimproved	Histaminase alone
Allergic eczema	3	2 unimp. 1 imp.	Histaminase plus other therapy
Chronic urticaria	13	8 cured 5 imp.	Histaminase alone
Idiopathic pruritus	3	Slight improvement	Histaminase alone

Ten additional cases of chronic urticaria treated with injections of histaminase were all improved. Goldberg felt that the drug was a helpful factor in the treatment of allergic dermatoses. His patients who received intramuscular injections of histaminase had much better results than

those who received the enzyme in tablet form. In Goldberg's opinion, further clinical and laboratory data are necessary before any definite conclusions can be drawn concerning the specific value of the drug.

We have continued the use of histaminase in various dermatoses since our report in 1939, and can now add the data given in Table VII.

TABLE VII

Disease	No. of cases	Comment
Urticaria	35	21 clinically cured 14 unimproved
Acne vulgaris	7	No cases appreciably improved
Light sensitization dermatitis	1	Much improvement
Dermographism	2	No change
Atopic dermatitis	11	No improvement

In all of the cases of urticaria which did not improve, the drug was continued for one month, and in acne for two months. In the "cured" cases of urticaria, the time varied from four days to four weeks. The dosage varied from 60

to 120 histamine-detoxifying units daily (one unit represents the quantity of histaminase which is capable of detoxifying 1 mg. of histamine hydrochloride during twenty-four hours at a temperature of 37° C.).

As in our first group of cases of urticaria, those selected were of relatively long duration, and in most instances had proved refractory to the usual therapeutic measures. From personal experience with histaminase in the treatment of urticaria and study of the reports of other observers, it seems justifiable to state that the drug is of value in certain cases of this disease. Two-thirds of our cases to which histaminase was administered obtained satisfactory results.

THE SEARCH FOR UNITY

If we are to have a durable peace after the war, if out of the wreckage of the present a new kind of coöperative life is to be built on a global scale, the part that science and advancing knowledge will play must not be overlooked. For although wars and economic rivalries may for longer or shorter periods isolate nations and split them up into separate units, the process is never complete because the intellectual life of the world, as far as science and learning are concerned, is definitely internationalized, and whether we wish it or not an indelible pattern of unity has been woven into the society of mankind.

There is not an area of activity in which this cannot be illustrated. An American soldier wounded on a battlefield in the Far East owes his life to the Japanese scientist, Kitasato, who isolated the bacillus of tetanus. A Russian soldier saved by a blood transfusion is indebted to Landsteiner, an Austrian. A German soldier is shielded from typhoid fever with the help of a Russian, Metchnikoff. A Dutch marine in the East Indies is protected from malaria because of the experiments of an Italian, Grassi; while a British aviator in North Africa escapes death from surgical infection because a Frenchman, Pasteur, and a German, Koch, elaborated a new technique.

In peace as in war we are all of us the beneficiaries of contributions to knowledge made by every nation in the world. Our children are guarded from diphtheria by what a Japanese and a German did; they are protected from smallpox by an Englishman's work; they are saved from rabies because of a Frenchman; they are cured of pellagra through the researches of an Austrian. From birth to death they are surrounded by an invisible host—the spirits of men who never thought in terms of flags or boundary lines and who never served a lesser loyalty than the welfare of mankind. The best that every individual or group has produced anywhere in the world has always been available to serve the race of men, regardless of nation or color.—RAYMOND B. FOSDICK: The Rockefeller Foundation—A Review for 1941.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

Frank C. Andrus, Pathologist

Presentation of a Case

DR. J. STRICKLER: The case is that of a sixty-one-year-old white male who was admitted to the Psychiatric Service of the hospital on April 17, 1942. At that time he was comatose, unresponsive, and was unable to swallow food or drink water. He was said to have developed pain in his back about eight months previous to admission which gradually had become worse. The pain radiated to the lower costal margin and particularly in the lumbo-sacral region.

DR. G. FAHR: So there is the history of fairly diffuse pains. Did he give a history of pain in his bones; did anyone get that?

DR. STRICKLER: He complained of pain in the back and anterior lower costal margin. We could not tell for sure whether the pain was in the upper abdominal region or lower chest.

DR. E. T. BELL: Did he complain that it increased on breathing or bending over?

DR. STRICKLER: Later he refused to move; any movement caused severe pain.

DR. F. ANDRUS: Was he mentally clear when you examined him?

DR. STRICKLER: Not when I saw him. We couldn't get anything out of him and he did not respond to questioning. On motion he would groan and complain incoherently.

DR. STRICKLER: He was studied on two occasions in another hospital in November and December of 1941 for two weeks at a time. X-rays were taken and Paget's Disease or hyperparathyroidism were considered. He was given a series of injections of arthritis vaccine with no effect. Late in January, 1942, he became debilitated and refused to move. He complained of extreme pain when anyone tried to move him or care for him. A week before admission he became comatose and unresponsive. He was seen by a psychiatrist who sent him into the hospital and that accounted for his admission to our Psychiatric Service. He could not swallow and he had to be fed through a nasal tube.

Physical examination revealed a systolic murmur at the apex which was not transmitted. The blood pressure was 132/80. The skin was brownish and was discolored, particularly over his face. He made facial grimaces and complained whenever he was moved.

Laboratory data: The hemoglobin was 41 per cent and the leukocyte count was 7,700. The urine contained two plus albumin, 25 to 20 red cells, and 75 to 80 white cells per high power field. The blood urea nitrogen was 121.8 mg. per cent and the creatinine 5.7 mg. per cent at the time of admission. On April 23, 1942, the blood urea nitrogen was 132.9 mg. per cent and the creatinine 6.8 mg. per cent. Plasma proteins were determined on two occasions and were found to be 11.5 grams per cent and 10.96 grams per cent. The fibrinogen was .479 gram per cent, globulin 8.075 grams per cent, and albumin 2.4 grams per cent. Treatment was limited to keeping up the fluid intake. He expired on April 24, 1942.

DR. BELL: What was his urinary output?

DR. STRICKLER: About 30 to 50 c.c. per day.

DR. BELL: That is the usual finding, oliguria.

DR. FAHR: What was the specific gravity of his urine?

DR. STRICKLER: It was 1.015 on two occasions. We looked for Bence-Jones protein in the urine but it was absent.

DR. BELL: It is absent in about one-third of these cases. Now the problem here for the clinician to determine is why this man had uremia. I remember one case that had a protein of 13 with no urinary disturbances whatever. There was no renal insufficiency. Some of the patients, however, develop uremia. There are three reasons for this. One is the plugging with casts which causes anuria or oliguria. Another is that some incidental renal disease is present, like pyelonephritis. The third is that just what we have today which is only the second case in the literature.

DR. ANDRUS: Dr. Strickler, what led you to take the plasma proteins?

DR. STRICKLER: His anemia was the main thing.

DR. ANDRUS: I was interested in this case because the technician was concerned by the high level of the plasma proteins. The blood plasma was so viscous that it would hardly run from a pipette. When I learned the high level I was sure that we were dealing with a case of multiple myeloma.

CASE REPORT

DR. GRATZEK: The x-ray films show striking changes. The skull plate is especially highly characteristic of multiple myeloma.

DR. FAHR: How can you tell them from other metastatic lesions?

DR. F. GRATZEK: Because they are rounded. Of course, other conditions such as Schuller-Christian's disease give findings like these. There are also rounded areas of rarefaction in the ribs, upper femora, pelvis, and scapulae and clavicles.

Autopsy Findings

DR. R. PAPERMASTER: The chief findings were limited to the bones and kidneys. The kidneys were enlarged to about twice their usual size. The ribs and sternum were soft and fractured very easily. They contained nodules which were soft and which destroyed the surrounding bone.

Microscopic Findings

DR. ANDRUS: Sections of the bone marrow have the structure that we ordinarily see in multiple myeloma.

The tumor mass is made up of plasma cells. The cells have an eccentrically placed nucleus and a basophilic cytoplasm. We should mention that there is one type of multiple myeloma which does not give these discrete punched-out areas but involves the bones diffusely. If you don't examine bone marrow in such a case, you might miss the diagnosis.

DR. BELL: The kidneys show nothing but cloudiness grossly and no diagnosis can be made from that. They were enlarged. The first thing that we want to look for is to see if there are any casts in the tubules. The tubules are not dilated here. In most cases we get uremia because there are so many casts that the whole kidney is plugged. In these kidneys there are quite a number of casts but not enough to obstruct the kidneys. In the cortex there is shrinkage of the tubules. The glomeruli appear to be avascular and there is disuse atrophy of the tubules; they are not getting enough to do. There is no glomerulonephritis but a precipitation of protein in the glomerular capillaries which decreased the glomerular filtration. That is why this patient developed oliguria and uremia.

CASE REPORT

MASSIVE NON-NEPHRITIC EDEMA FOLLOWING RESPIRATORY INFECTIONS

J. ALLEN WILSON, M.D., Ph.D.

Clinical Assistant in Medicine, University of Minnesota Medical School
Saint Paul, Minnesota

IN THIS report I shall describe two patients exhibiting a form of edema which I have never seen previously and which I have not found completely described in the literature covering edema. The edema, in both cases in my opinion, is extrarenal in origin.

Case 1.—A male physician, then thirty-seven years of age, developed in December, 1938, an acute laryngitis and bronchitis. He did not stop work but took some steam inhalations and used generous doses of an expectorant cough syrup containing calcium iodide, ephedrine and nembital. After five days he became severely nauseated and vomited several times in a twenty-four-hour period. This was thought probably due to the action of the iodide. No diarrhea occurred. Mild upper abdominal cramps and tenderness were felt for the next few days. The iodide expectorant was stopped (the bronchitis having improved just before the nausea appeared) and the abdominal discomfort disappeared, to be followed (ten days after the onset of the original infection) by a generalized pitting edema, most marked in the lower extremities. His weight increased thirteen pounds within a week. Physical examination revealed no abnormalities of the heart or lungs. He entered a hospital where the laboratory tests were as follows:

1. Repeated urine examinations showed no albumin or abnormal microscopic constituents. A trace of sugar

was seen once. All urine specimens were acid in reaction and their specific gravity ranged from 1.015 to 1.020.

2. Blood examination showed: hemoglobin 90 per cent; white blood count 8,300 to 9,300; differential count normal.

3. The blood urea nitrogen was 13.1 mgm.; the blood sugar 126 mgm.; blood chlorides 500 mgm.; blood calcium 8.3.

4. The basal metabolism rate was minus 1 per cent.

5. A chest roentgenogram showed a normal heart shadow and no lung disease.

6. An electrocardiogram was normal.

The blood pressure was 124-78. There was no fever present at any time.

The patient was given a low salt diet, and fluids were limited to 1,200 c.c. daily. He was placed on six grains daily of desiccated thyroid and three grams daily of ammonium nitrate. (The physician in charge added the thyroid although the edema in no way suggested a myxedema.)

Within three days time the patient lost over thirteen pounds of fluid with a copious diuresis. He left the hospital and resumed work. There has never been a recurrence of this edema in the succeeding two and a half years, and he has remained in excellent health.

Case 2.—A married woman, a housewife, fifty-seven years of age, was seen by me on January 13, 1941. Three weeks previously she had developed abdominal cramps, diarrhea of four to six stools daily, and had vomited

Read before the meeting of the Minnesota Society of Internal Medicine, Minneapolis, May 17, 1941.

several times at the onset (similar to the infectious gastro-enteritis cases we were seeing frequently last winter). No blood or mucus was seen in the stools. A week before I saw her she developed a severe head cold and two days later a severe cough with subnormal tightness and the expectoration of considerable mucus. With the onset of this head cold and bronchitis she developed a generalized edema, most marked in the lower extremities. She had never had this before except that for many years a slight edema of her ankles would appear if she remained on her feet for several hours.

Her weight had increased in the past week from 184.5 to 202.5 (a gain of 18 pounds).

Physical examination revealed inflammation of the pharynx and uvula. No cardiac enlargement was determined on percussion. No heart murmurs were heard. Numerous mucous râles were heard through both lung bases posteriorly. Her abdomen was obese but I thought there was a small amount of ascites present. A massive pitting edema was present in the lower extremities extending well up onto the thighs.

Laboratory.—1. Urine alkaline; specific gravity 1.007; no albumin, sugar or abnormal elements.

2. The hemoglobin was 76 per cent (13 gms.); red blood cell count 4,410,000; white blood count 6,350 to 12,400.

3. The Wassermann test was negative; the blood cholesterol 220 mgm.; blood urea nitrogen 10 mgm.; blood sugar 102 mgm. The sedimentation rate was 57 mm. in one hour.

4. The chest roentgenogram showed a transverse type of heart measuring 52 per cent of the chest diameter, and very prominent bronchial markings indicative of bronchitis.

The temperature was 99.9; pulse 84; blood pressure 142-80.

This patient could not afford hospital care and being from out of town was not eligible for Ancker Hospital, so she was kept in bed at the home of her daughter. A salt free diet was given and her fluids restricted to 1,000 c.c. daily. She was given nine grams daily of potassium nitrate and a mild expectorant cough syrup without ammonium chlorides or iodides in it.

She passed two quarts of urine in the first twenty-four hours and another three quarts in the second twenty-four hours. In one week after beginning this treatment her weight dropped fifteen pounds and the patient returned to her home. A recent letter states that her edema has not returned.

Comment

To explain the occurrence of edema in these two cases, one must look for causes outside the kidney. According to Rehberg,⁵ albuminuria is one of the symptoms in practically all diseases of the kidney. An almost constant finding in nephroses is cholesterinemia. Neither patient had albuminuria and in the one whose blood cholesterol was determined it was normal. In all diseases studied where extracellular edema is known to exist (kidney disease, heart disease, ascites, hydrothorax, anemia, beriberi, nutritional or hunger edema), the cause of the edema may be:

1. Decreased colloid osmotic pressure of the blood;
2. Increased capillary pressure (as in heart disease);
3. Injured abnormally permeable capillaries.

As long as these three factors are normal, Rehberg believes extracellular edema will not be formed.

Unfortunately in neither case were the plasma proteins determined. However, normally the colloid osmotic pressure of the blood is 350-400 mm. of water and edema does not occur in nephritis or nephrosis until this is lowered to 250 mm. of water. This drop is due

to the loss into the urine of small molecules of plasma albumin which exert a high osmotic pressure. I believe that the absence of albuminuria in these two cases points against a change in blood osmotic pressure as being a factor in their edema.

Increased capillary pressure, which is the chief cause of edema with heart disease, can be ruled out here.

Increased permeability of the capillary walls is a transient condition and according to Snowden⁶ is seen in the early stages of acute nephritis or in similar toxic states, especially in streptococcus infections. The blood proteins are not reduced but Fishberg¹ states that the edema fluid must show considerable amounts of protein in order to assume increased capillary permeability. Glomerular capillaries, of course, may be included, causing albuminuria, but it is theoretically possible to have some increased capillary permeability with edema but no albuminuria.

I believe that the factors of sodium chloride and water intake must be considered carefully in explaining these two cases of edema. Leiter³ in discussing chronic nutritional edemas describes in addition to a chronic damage from gradually developing emaciation and a slow fall in the plasma proteins, an acute insult which is due to a temporary severe diarrhea or some infection followed by a period of relatively huge intake of salted fluids (such as soups) to appease the urge for food; edema appears quickly. If plasma proteins are not too low, rest in bed and restriction of fluids and salt dispel the edema. Hastings² points out that edema fluid can be formed only to the extent that salt and water are available for its formation. Where a so-called tendency to edema is present, the ingestion of relatively slightly increased amounts of salt causes edema. Withholding water and salt in these cases often prevents edema.

My explanation of these two cases of edema then includes:

1. A possible increased permeability of the capillaries due to infection.
2. Increased intake of water.
3. Increased sodium chloride intake. In one case the patient admitted being a heavy user of salt normally. In the other case the patient consumed extra amounts of heavily salted soups, salted butter, etc.
4. In one patient effervescent alkalies were also used, during the days preceding the onset of the edema. The sodium ion is known to favor retention of fluids and decreased urine output (Reed).⁴

In both patients prompt diuresis followed the limitation of fluids, restriction of sodium chloride and the use of adequate amounts of ammonium nitrate or potassium nitrate, respectively. No recurrence of edema has been had by either patient.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF THE MINNESOTA STATE MEDICAL SOCIETY

By **ARTHUR S. HAMILTON, M.D.**
Minneapolis, Minnesota

(Continued from May Issue)

Eleventh Annual Meeting

The eleventh annual meeting was held in Saint Paul on June 17, 1879, the president, Dr. J. E. Finch of Hastings, presiding.

About forty members were present at the opening session, but this number was subsequently considerably increased by the election of twenty-one new members.

The medical and surgical papers presented at this meeting resemble those presented the year previously, but the surgical cases presented, while all case histories, were a little more varied and included other than emergency cases. Although these papers were undoubtedly interesting to those present, there was nothing in them that would interest a physician today, except for their novelty. The retiring president's address was largely devoted to therapeutics and materia medica. Dr. Finch did briefly mention Koch's work on micro-organisms, but stated that the investigations were inaccessible to the practitioner.

Twelfth Annual Meeting

The twelfth annual meeting was held in Albert Lea on June 15, 1880, in the Masonic Hall. Twenty-three new members were admitted. At this meeting, for the first time apparently, an exhibit of microscopic sections of tissue was shown. Microscopes were also exhibited and an essay was read on the use of the metric system in writing prescriptions. An amendment to the constitution was presented providing for the admission of women physicians to membership. After a prolonged debate the amendment was passed by a vote of 39 to 3 and women belonging to the Ramsey County Medical Society were admitted.

The address of the president, Dr. A. C. Wedge of Albert Lea, was short and contained nothing of medical interest. Dr. E. J. Abbott of Saint Paul, as chairman of the Committee on Surgery, read an address in which he reviewed the new advances in surgical technique. "The committee", he said, "made inquiries in regard to antiseptics, but so far have been unable to learn of a single case in which the Lister method has been followed in this state. We think a large number of the members use disinfectants to some extent, i.e., carbolized water for washing wounds, et cetera, and some use carbolized gauze as a dressing." He then discussed Listerism and stated that Mr. Lister in answering criticisms of his technique said that hygienic conditions varied with the different surgeons for or against the method. Mr. Spence, for instance, had his wards cleaned every year, while the wards of Lister were allowed to go uncleaned for three or four years, "an admission which does not reflect much credit on the antiseptic advocate."

It seems that more is claimed for the Lister treatment than it really deserves." He also mentions the use of the Bigelow lithotrite and the use of hot water and hot compresses in arresting capillary hemorrhage in wounds, a method which he warmly recommends. This appears not to have been in general use up to that time.

Most of the surgical cases reported were short, being nothing more than reports of patients attended. Dr. Abbott remarked during the session that but few had responded to the request for reports of surgical cases. Dr. Daniel Leasure of Saint Paul read a long paper on "The Law of Heredity" and there was a report by Dr. C. H. Salisbury, chairman of the Committee on Medical Jurisprudence, on a medical legal case. The constitution of the Society underwent a radical revision and the necessity for careful examination of the patient and a critical evaluation of the symptoms was more carefully considered.

Thirteenth Annual Meeting

The thirteenth annual meeting of the Minnesota State Medical Society was held in Saint Paul, June 21 and 22, 1881. Dr. C. H. Hewitt of Red Wing presided. Twenty-seven new members were admitted to the Society and Dr. A. J. Stone was elected president for the ensuing year.

Numerous amendments to the constitution were proposed, and Dr. Daniel Leasure, president of the Ramsey County Medical Society, in his address of welcome, noted that "There is a great diversity of opinion amongst leading surgeons as to all that is claimed for Listerism." He also criticized many physicians who "are already looking for a medicine that will *cure*, instead of trying to understand the true nature of the perverted life force that we call disease."

A dozen surgical cases were discussed by Dr. C. A. Wheaton of patients who had been under his care. These were much better presented and discussed by him than any heretofore brought before the Society.

The Committee on Diseases of Children submitted many reports of childhood disease and presented a long discussion on summer diarrhea.

This meeting was superior to those of the preceding years and the science of medicine was becoming more modern. The Society now had a membership of one hundred and seventeen. Six honorary members and twenty-seven active members had died since the Society was organized.

Fourteenth Annual Meeting

The fourteenth annual meeting of the Minnesota State Medical Society was also held in Saint Paul, June 6 and 7, 1882, Dr. A. J. Stone of Saint Paul, presiding. Dr. P. H. Millard of Stillwater was elected president for the coming year. Fifty-six new members were elected.

The Society did no constructive business at this session as the American Medical Association was meeting in Saint Paul at the same time and the committee reports were presented by title and ordered printed.

Dr. C. H. Hewitt presented an excellent address on "The Problem of Medicine as a Professional and Practical Art." This was discussed in many phases and certainly must have made a strong impression on his hearers.

The Committee on Diseases of Children made a long report, covering mostly gastro-intestinal conditions. As there was no understanding at that time of the part played by bacteriological contamination of milk, there was nothing in the report of interest to us now.

A large number of surgical histories were presented by Drs. McGaughey,

Wheaton, Hewitt, Dunsmoor, Dunn (who was then in Shakopee), R. L. Moore, Dedolph, R. W. Hunt, D. A. Stewart, L. H. Munger, D. W. Hand, W. W. and W. M. Sweney, F. E. Bissell, A. T. Conley, C. Berry and H. L. Coon. One can see from the numerous contributors to this committee's report that surgery was advancing rapidly, as many of the surgeons reported the use of carbolic acid and carbolized catgut in the treatment of their cases.

The reports of the Committees on Obstetrics, Gynecology and Nervous Diseases were short, but that of the Committee on Epidemics was largely composed of a review of the work and activities of the State Board of Health, commending its activities and suggesting that the work of the Board be extended and that the Legislature of the State give it more power.

The Committee on Medical Jurisprudence made an extensive report, written by its chairman, Dr. C. H. Boardman, on "Medical Expert Testimony." The same discussion that is indulged in today regarding the subject was adequately presented and remedies proposed. Dr. J. H. Dunn read a paper entitled "Notes on a Suit for Malpractice." This was a long report, in which he gave the court testimony of Dr. J. H. Murphy of Saint Paul, who appeared as an expert in a case tried before the court in Shakopee. Certainly Dr. Murphy's testimony was contrary to ideas entertained by surgeons then and now. As Dr. Murphy was a witness for the defense, perhaps it is not difficult for one to understand his attitude. Dr. Dunn surely had considerable courage to present the paper and castigated Dr. Murphy as he deserved.

Dr. Brewer Mattocks, then in Faribault, presented a statistical report on "Consumption in Minnesota."

The members of the Society were invited to attend the reception given by Hon. D. M. Sabin and the citizens of Stillwater to the members of the American Medical Association, who were in Saint Paul for the national meeting at that time.

Fifteenth Annual Meeting

The fifteenth annual meeting of the Minnesota State Medical Society was held in Minneapolis, June 19 and 20, 1883. The president, Dr. P. H. Millard, of Stillwater, delivered his presidential address and Dr. W. L. Lincoln of Wabasha was elected president for the ensuing year. Fifty-seven new members were admitted to the Society.

Dr. Talbot Jones offered a resolution, which was unanimously adopted, requesting the government to adequately house the Army Medical Library which, then as now, was in an overcrowded and non-fireproof building.

Doctor Millard, in his presidential address, stressed the part that bacteriological research was playing in medicine. He also stated that the part played by bacteria in specific diseases was now recognized, adding "We hope denunciations of Listerism have quite reached their climax, and we prophecy for the memory of this distinguished surgeon a fame second to none." He also protested against the tendency of young men to favor too early in their careers the practice of a specialty, a decision which he considered a great mistake.

"The members of this Society are undoubtedly all aware that the last session of the Minnesota Legislature passed a 'Medical Practice Act', the penalties of which become operative after December 31 this year. I believe, gentlemen, this is a very fair bill and abreast of any act now in force in any of the states."

Dr. C. E. Riggs presented a long and carefully prepared paper on "Functional Disease of the Nervous System", which was well received, and Dr. A. W. Abbott again attacked the subject of "Diphtheria" which was then as it was until a

decade or so later, a subject of paramount interest because of its mortality. The subject was mainly confined to treatment by tracheotomy.

A committee appointed to outline measures for improving the annual transactions of the Society requested that the practice of presenting reports of cases and operations be abandoned as such are little more than a catalogue of the achievements of members of the Society and, so far as they contribute nothing to the knowledge of members, are of no real value. It was urged that reports be not a mere recapitulation, but original papers. This certainly was a step in advance as the surgical histories heretofore presented in most cases were nothing more than a list of operations performed.

Dr. C. N. Hewitt made a report on the prevalence of diphtheria and typhoid fever in the state from 1872 to 1881. In 1872 there were forty-two deaths from diphtheria reported and in 1881 the number was 1,397. That of typhoid fever rose from 315 in 1872 to 711 in 1881. Dr. Hewitt implored the physicians of the state to join with the Board of Health in an endeavor to control these epidemics. In another report by Doctor Hewitt he read the act to regulate the practice of medicine as passed by the Legislature and mentioned the part the University of Minnesota was to play in the act.

Dr. C. A. Wheaton presented a well thought out paper on "Shock as Related to Surgical Operations", especially to surgery performed following railway injuries.

Sixteenth Annual Meeting

The sixteenth annual meeting of the Minnesota State Medical Society was held in Stillwater, June 19 and 20, 1884. Dr. W. L. Lincoln, the president, delivered the annual address, which was mainly an appeal to the members of the Society to engage actively in the promulgation of the doctrines of hygiene and of preventive medicine, and to study carefully the relations between inebriety and heredity, with a view to the accumulation of reliable information upon this important subject.

Changes in the reports made by the various committees were discussed and it was decided that these reports should be edited, printed and distributed before the annual meeting so that they could be adequately discussed at the meeting. By this method it was hoped that many inadequate and too brief reports could be eliminated.

The meeting was not very well attended, possibly because the location was not very favorable. Many of the committee reports were read by title and were ordered printed in the transactions.

Doctor Millard, in reply to a question as to what had been accomplished by the State Board of Examiners, stated that he had the addresses of more than two hundred persons practicing medicine who have left the state since the enactment of the law, because of its requirements. He said that the Board would endeavor to protect the profession and to raise the standard of professional excellence in the state, and asked the Society to aid and countenance them in their efforts.

Herniotomy and the radical cure of hernia were discussed by Doctors Millard, Hunter, Moore and others. Doctor Staples described a treatment of hip joint disease by means of a leather splint.

The Committee on Obstetrics indulged in a long discussion of the value of irrigation and intra-uterine injections; no agreement was reached as to which procedure was proper.

Dr. J. B. McGaughey of Winona was elected president for the ensuing year and sixteen new members were elected to membership.

Dr. C. H. Hunter, in his report of the Committee on Surgery, stated that while abdominal surgery was still the chief work of the surgeons but one report of surgery of the kidney in the state was known. Since his report had been written, however, Dr. French had performed the operation of nephrotomy. The patients in both cases died.

The Committee on Nervous Diseases selected hysteria as the subject of its report and a number of physicians reported histories of patients. The treatment of diphtheria was again taken up by the Committee on Diseases of Children and medicated steam inhalation seems to have been the newest procedure.

Seventeenth Annual Meeting

The seventeenth annual meeting of the Minnesota State Medical Society was held in Saint Paul, June 18 and 19, 1885. Forty-two new members were admitted to the Society. Doctor McGaughey, in his presidential address, stressed the crying need for more scientific investigation of the causes of preventive disease. "If we except smallpox there no serious disorder of which it can truly be said that we possess the power to entirely prevent its appearance, or even to restrict it within prescribed limits when it does appear."

The changes in the constitution proposed at the last meeting were adopted and Doctor Dunsmore moved that the various sections be eliminated and that but two sections, Medicine and Surgery, be substituted. This was carried.

Dr. E. J. Davis of Mankato was elected president for the ensuing year.

In the Section on Surgery Doctor Dunsmore reported three patients with suppurative perityphilitis. In two of them he operated three weeks after the sudden attack and drained the abscess. In the third patient the pus sack ruptured into the bowel. Recovery occurred in all three patients.

Diphtheria, as in previous meetings, was reported upon but no definite means of handling the disease was apparent. Its prevalence and the high mortality following its advent in a community had made it a major item for consideration.

Dr. W. W. Mayo and Dr. W. J. Mayo reported a number of surgical patients under their care and the good results following treatment and care. Since cholera was now present in Europe Dr. Talbot Jones read a paper on the subject, giving a summary of the knowledge of the disease and what sanitary measures should be adopted, should the disease reach this country. He stated that the disease had on two different occasions in the past appeared here when it was prevailing elsewhere in the country.

Eighteenth Annual Meeting

The eighteenth annual meeting of the Minnesota State Medical Society was held in Minneapolis, June 17 and 18, 1886. Forty-two new members were admitted and Dr. H. H. Kimball of Minneapolis was elected president for the coming year.

There was some criticism on the methods of the Committee on Membership in determining the status of applicants. Doctor Millard stated that on July 1, 1883 there were 1,160 practitioners of medicine in the state, of whom more than one-third were not regular graduates. The five-year exemption clause enabled 119 to remain in the state; 260 were compelled to leave. At present there were only 995 practitioners in the state. Of these, seventy-two remained under the five-year exemption clause. During the life of the Board it had examined about eighty for licenses, but had licensed only one. Traveling quacks were now almost unknown. The Board refused to recognize the diplomas of

seventeen schools. In answer to a question, Doctor Millard stated that a license could be rescinded if the licensee afterwards showed himself unfit to hold it.

There was considerable discussion on what constitutes a sufficient course of medical education. It was decided that the Legislature should pass a more drastic law governing the admission of practitioners in the state.

The papers read at the meeting were largely reports of the patients under the care of individual physicians or the number of particular cases in which operation had been performed, or medical patients attended.

Nineteenth Annual Meeting

The nineteenth annual meeting of the Minnesota State Medical Society was held in Duluth, June 16 and 17, 1887. The president, Dr. H. H. Kimball, being absent, Dr. W. L. Beebe of St. Cloud, as vice president, presided and Doctor Kimball's address was read by the secretary.

The Transactions for this year were considerably smaller than those of several previous years, this being due to the amendment to the constitution submitted by Dr. A. W. Abbott that "the Committee on Publication select from the papers presented such papers as have sufficient scientific and literary interest to warrant their publication."

The papers selected for publication were much longer and better written than those heretofore published. We note particularly those of Doctor Millard on "The Treatment of Strangulated Hernia" and Dr. James H. Dunn, who had moved from Shakopee to Minneapolis, on "A Decade of Observations and Experiences in Antiseptic Surgery." The former presented nine cases and the latter, sixty-one. Doctor Dunn concluded his presentation, "I almost feel that an apology is due for considering at this late day the subject of antiseptic wound treatment, when to scientific surgeons there is but one side to the question. My excuse is solely that so large a percentage of general surgery is still denied the benefits of this great advance of the past two decades."

Dr. C. F. McComb of Duluth was elected president to succeed Doctor Kimball and twenty-two new members were admitted. This was the first meeting of the Society held in Duluth.

Twentieth Annual Meeting

The twentieth annual meeting of the Minnesota State Medical Society was held in Saint Paul, June 21 and 22, 1888. Doctor McComb, in his presidential address, confined his remarks mainly to medical education and the inauguration of medical teaching by the University of Minnesota. He hoped that the efforts of the University would be successful and that the professional excellence of the staff would rival any of our eastern colleges and would be a source of pride to all.

The volume of Transactions of this year was less voluminous than that of the previous year, notwithstanding the fact that several of the previous year's papers were included because they did not reach the committee in time for publication the year before.

There was a well thought out essay by Dr. F. Allport of Minneapolis on "Thoughts on Medical Progress" and one by Dr. Burnside Foster on "Personal and Public Prophylaxis Against Infectious Disease." Dr. W. J. Mayo wrote on "Inflammations Involving the Caecum, Its Appendix or Both." His conclusions and operative treatment were similar to those reported by Doctor Dunsmore at the 1885 meeting.

Dr. A. MacLaren of Saint Paul presented an essay on "The Etiology of Chronic Ovaritis with Reports of Cases." For some strange reason his name does not appear as a member of the Society. Another well presented essay by Dr. W. A. Jones of Minneapolis on "Localization in Disease" dealt with the localization of lesions of the nervous system and he illustrated his essay with a number of case histories of lesions of the nervous system.

Dr. C. A. Wheaton of Saint Paul was elected president for the ensuing year and twenty-five members were accepted to membership.

Twenty-first Annual Meeting

The twenty-first annual meeting of the Minnesota State Medical Society was held in Minneapolis, June 20 and 21, 1889. Doctor Wheaton, as president, presided at the opening session, but being unable to attend the second day he was succeeded in the chair by Dr. H. H. Wilcox, the second vice president. Forty-one new members were admitted to the Society.

A committee was appointed to revise the constitution and by-laws and to report at the next meeting. It was voted that the meetings be extended to three days instead of two, with but two sections—Medicine and Surgery, as voted upon at the seventeenth annual meeting. A stenographer was engaged to report the discussions of papers presented at the meeting, but not being familiar with technical terms, after a short trial he refused to continue.

Considerable discussion took place regarding the charges made against Doctor Bowers, superintendent of the St. Peter Insane Asylum. Several motions were made but rejected, upholding Doctor Bowers and expressing sympathy for him. It was thought that since investigation was under way it was inopportune for the Society to pass such resolutions at the time.

In Doctor Wheaton's presidential address he first reviewed the history of the Society, stating that at its organization meeting in 1869 the members numbered 119, all from the counties of Ramsey, Hennepin, Fillmore and Winona. Now its roster showed 357 active members. He then reviewed the advances made in sanitary legislation and medical licensing in the state and urged the members to aid and abet the State Board of Medical Examiners and the Board of Health. He stated that the doubts regarding the efficacy of antiseptic surgery had now passed and that omission of an antiseptic was equivalent to malpractice. He quoted statistics showing that since the adoption of antiseptics in surgery the mortality from various amputations had fallen from 52 and 39 per cent to 5 and 4 per cent. He regretted that many practitioners still were not using antiseptic precautions, adding, "He of the profession who fails to make the effort in this particular is jeopardizing his peace of mind in this world and compromising his eternal happiness."

Most of the papers presented at this meeting were surgical and those on gynecological and obstetrical subjects dealt largely with surgical aspects. Dr. W. W. Mayo discussed "Prostatic Hypertrophy and Its Treatment" and Dr. P. H. Millard spoke on "Intubation in Diphtheria." Medical education was also represented by several papers, notably perhaps because the many schools of medicine in the state had now closed, leaving the University School of Medicine practically unique.

A paper by Dr. Thomas McDavitt of Winona on "Acne Vulgaris" now seems rather amusing. He advocated the use of cold sounds as a treatment and cited cases showing its efficacy. The treatment was not original with him.

One notes that for the first time in Transactions of the Society the dis-

cussions of many of the papers are printed. Also for the first time, a paper definitely pathological in theme was presented by Dr. J. Clark Stewart of Minneapolis, with the specimens described.

Dr. J. H. Dunn of Minneapolis was elected president for the following year, winning the election by one vote over Dr. G. W. Wood of Faribault.

Twenty-second Annual Meeting

The twenty-second annual meeting of the Society was held in Saint Paul, June 19, 20 and 21, 1890. Dr. Dunn, as president, presided the first day but was absent on the succeeding days as were also the vice presidents. The secretary, Dr. C. B. Witherle of Saint Paul, therefore, presided.

The Committee on Revision of the Constitution and By-laws reported and the Constitution as revised and presented by the committee was accepted. The treasurer, Dr. Sheardown of Stockton having died during the preceding meeting, the acting treasurer, Dr. Witherle, presented the treasurer's report. Dr. W. L. Beebe of St. Cloud was elected president for the succeeding year. Twenty-four new members were admitted to membership.

The Transactions for this year were printed in a small imperial octavo form with pages in double column arrangement, by the Northwestern Lancet Company. It is evident that the papers presented had been published in the *Lancet*.

One cannot comment on all the papers presented but one should read the presidential address of Doctor Dunn. It is a long address and thoroughly covers the state of medicine at the time it was presented. It must have been very favorably received by his hearers. Notable essays were read by Drs. J. W. Bell, J. W. Andrews, C. L. Wells, J. H. Stuart, C. G. Slagel, J. W. MacDonald, C. H. Mayo, W. J. Mayo, Justus Ohage, C. A. Wheaton and Archibald MacLaren, and James E. Moore. In Dr. Moore's essay on "When Shall We Operate in Perityphlitis?" he uses the word "appendicitis." The early operation for appendicitis had not yet come, however.

All the papers presented at this meeting were much superior to any heretofore presented. Medicine was becoming, aside from laboratory researches, quite modern. The discussions of the papers, except in one case, were not printed.

(To be continued in the July issue.)

President's Letter

MEDICAL INVESTMENTS: SUMMER ROUND-UP

I

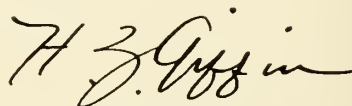

ALL of us who can do so will, I am sure, arrange to attend our Annual Meeting in Duluth. Medical education is the doctor's best investment. The value of his capital may be affected by low interest rates, his net income may be reduced by higher taxes, his purchasing power may suffer as a result of the increased cost of commodities, and the value of his real estate and securities may dwindle with the circumstances of conflict and the flux of events. But fortunately a professional man's knowledge of his profession and his accretions to that knowledge maintain their value irrespective of external factors. Money spent for books and postgraduate courses, for visits to hospitals and clinics, and for attendance at medical meetings yields a spiritual sense of comradeship, an intellectual satisfaction from increasing knowledge, and a practical preparation for more effective service in a field where there is so much to learn and to give. The monetary rewards of the future will be decided by the value of the service as determined by the economic factors of the future rather than those of the past. They will be in line with the future cost of living, whether inflation or deflation supervenes. These are the reasons one can say that medical education is the doctor's best investment.

II

Mrs. Norman H. Baker, chairman of the Health and Summer Round-up of the Minnesota Congress of Parents and Teachers, requests the coöperation of physicians and local medical societies in the Summer Round-Up, which is a state-wide effort by the Parent-Teacher Association to encourage examination of younger school children by the family physician. Activities must develop rapidly so that remediable defects can be recognized and corrected during the summer months. The campaign will also stress immunization and vaccination and is especially applicable to children who expect to enter school for the first time this year.

The Committee on Child Health of the State Medical Association, under the chairmanship of Dr. R. L. J. Kennedy, has been actively interested. At a meeting of the Committee on February 28, a resolution was passed for approval by the Council in which it was recommended that, in collaboration with the State Board of Health and the Center for Continuation Study of the University of Minnesota, an institute be organized on the diseases of younger children. Representatives designated by each component society were to be asked to attend this institute. It was also recommended that each representative so designated by the local medical society continue to act as a liaison officer with the Parent-Teacher Association of the area covered by the society.

This resolution has been approved by the Council and plans have been made for instruction at the Center for Continuation Study from June 8 to 10. It is anticipated that a well-organized effort of this kind will expand the activities of the Summer Round-Up on a sound basis. The work requires coöperation with all local organizations interested and active in child health. The interest and services of physicians are essential to the success of the project, and plans of procedure must be worked out in each locality by representatives of the local medical societies and the Parent-Teacher Associations.

STATE MEDICAL MEETING

THE eighty-ninth annual meeting of the Min-
nesota State Medical Association will be held
at Duluth the last of this month in spite of Hitler
and Nazidom. The program, which promises to
live up to the high standard set by our Associa-
tion in past year, appears in this issue of the
JOURNAL.

It will be seen that the scientific program is to
be run in two sections held simultaneously
throughout the three days of the convention.
With both sections held in the Armory, one can
easily step from one to the other.

Round-table discussions, which have become
popular and seem to aid rather than inhibit diges-
tion, will be extensively used at the coming
meeting. Some eleven Round Tables, each seat-
ing twenty-five guests, will be conducted both
Tuesday and Wednesday noon.

Minnesota talent will be supplemented by visi-
tors brought through the courtesy of the Min-
nesota Radiological Society, the Northern Min-
nesota Medical Association, the Northwestern
Pediatric Society and the Minnesota Academy of
Ophthalmology and Otolaryngology. The last
mentioned society will furnish much of the pro-
gram the last day of the convention with clinics
at Saint Luke's Hospital in the morning and an
open meeting at the Armory in the afternoon.

The hospitality of Duluth is well known—the
climate, too. While the rest of the state may be
sweltering at the time of the meeting, Duluth is
not likely to be. The weather for the golf tourna-
ment the Sunday preceding the session can
almost be guaranteed to be perfect, as far as
temperature is concerned. A trip to Duluth can
easily combine duty and pleasure.

INDUSTRIAL HYGIENE

THE winning of the war will depend on pro-
duction as well as the performance of our
armed forces. For full production, the health of
the workers is an important consideration. As
Dr. Bristol brought out in his address before the
Hennepin County Medical Society,* the indus-
trial physician, whether full time or a general
practitioner on part time, plays an important
part in maintaining the worker on his job.

Not so long ago a physician who took an in-
dustrial job was looked down upon if not faced
with ostracism by his medical confreres. Indus-
trial work is approaching a specialty of phy-
sicians trained to do this work on a full time
basis for the larger corporations. However, in-
asmuch as some 85 per cent of industry is car-
ried on by comparatively small organizations, the
general practitioner will be called upon to supply

*See page 441.

this type of medical service for a long time to come. The general practitioner should, therefore, inform himself as to the functions of an industrial physician.

The male employe loses on the average some eight days a year, the female employe some twelve days, on account of physical disability. The greatest cause of disability is respiratory infection. Efforts have been made to reduce the incidence of colds by means of vaccines given hypodermically or orally without conclusive results. There is no better way of preventing the spread of respiratory infection than by exclusion of the infected employe from work during the acute stage. Those prone to repeated colds can easily be discovered and referred to specialists for possible remedial care.

There has been some misunderstanding as to the proper function of the industrial physician. In part at least he acts in an advisory capacity to the employe, referring him to his own physician for medical care. The closest coöperation should exist between the industrial physician and the rest of the profession as well as public health authorities. In the same way the general practitioner as well as the specialist can render a distinct service in the promotion of industrial health through the advice he gives his patient.

The prevention of venereal disease among industrial workers becomes of additional importance in localities in the vicinity of new industrial plants and army encampments. Army regulations serve pretty well to control infection of enlisted personnel. Physicians have a duty to perform in uncovering sources of infection in coöperation with police and local health authorities.

Education plays an important part in the matter of industrial hygiene. Millions of citizens are taking first aid and nutrition courses. While these courses will not make physicians or dietitians of the class members they are of value. Some will be better prepared to meet an emergency and all should learn the essentials in diet and that wholesale taking of vitamin preparations is an unnecessary expense. We do not feel that we can be rightfully accused of conceit, when we suggest that industry instead of placing reliance in providing vitamin tablets for its employes irrespective of need, would obtain a greater return from an equal expenditure by employing the services of a physician.

MEDICAL ENLISTMENT

UNCLE Sam needs more doctors and dentists and needs them now. In order to expedite the voluntary enlisting of members of these professional groups a medical recruiting office was established in the latter part of May at 496 Lowry Annex, Saint Paul, with Major C. A. Wood representing the Surgeon General and Major B. Groebner representing the Adjutant General.

A certain number of Minnesota physicians not now in service have signified their willingness to serve their country in its hour of need. Without doubt many others will make the decision to join when they realize the need.

All a medical man under the age of forty-five need do now is to call on Majors Groebner and Wood, fill out an application form and proceed to Fort Snelling for his physical examination. In fact, he may be sworn in by his new local Board at once. The usual waiting period of two or three months has thus been cut to two or three days. A period of two or four weeks is allowed, if needed, after being sworn in for settling of affairs at home.

This new Board has authority to dispense commissions—first lieutenantcies to those under thirty-seven and captaincies to those thirty-seven to forty-five. Recommendations for higher rank have to be sent in to the Surgeon General. This applies to physicians and dentists alike.

Until recently doctors married and with dependents have been put in Class III A. The latest ruling is that the pay of a first lieutenant is deemed sufficient for dependents and all doctors in good physical condition and under the age of forty-five belong in Class I A. When their draft numbers are called they will be drafted to serve a period of three months as privates and then possibly will be commissioned as lieutenants.

Uncle Sam has to have more medical men. During the last war about a third of the practitioners enlisted. The number of Minnesota physicians so far enlisted is indicated in the roster which appeared in MINNESOTA MEDICINE for May. The number hasn't nearly approached a third of the membership. Is the younger generation of medical men less patriotic than their fathers?

The determination of the personnel of the profession available for service and those essential

in their civilian locations has been left to the State and County Procurement and Assignment committees of the organized profession. The names of those approved are available to this new Board. It is to be earnestly hoped that enough medical men will enlist voluntarily to obviate the necessity of regimentation of the profession by the government, which could easily lead to state medicine following the present emergency.

MEEKER COUNTY TUBERCULOSIS PROGRAM

WHEN Dr. Chester H. Stewart, now head of the department of pediatrics of the University of Louisiana, was a member of the Council of the Minnesota State Medical Association for the sixth district, back in 1939, he made the suggestion that launched a program of tuberculosis control in Minnesota, which appears to be unique among the states.

As a result of Dr. Stewart's appeal to the Council, funds were appropriated by the State Medical Association and the Committee on Tuberculosis was instructed to set up plans. The plans took shape as a two-fold program.

First, the Meeker County experiment, recently described in *Collier's*, was launched. This experiment calls for the testing by use of the Mantoux tuberculin skin test of every resident in the county. Reactors are x-rayed without charge and active cases found are segregated and treated. The plan follows as nearly as possible the program of the veterinarians who began their county-wide testing of cattle for tuberculosis in Meeker County in 1923.

Second, definite standards for accreditation of each county for a measure of tuberculosis control were established and two counties, Lincoln in December, 1941, and Olmsted on May 22 this year, have already been awarded certificates of accreditation in accordance with the standards. This part of the program also follows the plan of the veterinarians whose accreditation program resulted in 1940 with the final accreditation of every county in the entire United States for control of tuberculous infection among cattle. The standards set by the committee were: (1) an average death rate on a five-year basis of 10 per 100,000 population or less; and (2) an infection rate among all high school seniors, as measured by the tuberculin test, of 15 per cent or less.

Dr. Stewart sat in on the preliminary meetings

of the committee in which the program took shape but left Minnesota to take over his present post at the University of Louisiana in New Orleans before the work actually got under way.

At the invitation of the committee he came back to Minnesota last month, however, to give the principal address at the accreditation ceremonies for Olmsted County which took place at the Rochester High School auditorium. On the same program were Mayor Paul Grassle, of Rochester, Superintendent Irvin E. Rosa of the Rochester public schools, Drs. S. E. Slayer, superintendent of Southwestern Sanitarium, E. A. Meyerding, secretary of the Minnesota Public Health Association, A. J. Chesley, secretary and executive officer of the State Board of Health, Donald C. Balfour, director of the Mayo Foundation, C. F. Schlotthauer of the Rochester Parent-Teacher Association and J. A. Myers, chairman of the State Committee on Tuberculosis.

Dr. H. Z. Giffin, president of the Minnesota State Medical Association, presented the certificate on behalf of the Association and of the State Board of Health which is coöperating in the undertaking. The certificate was signed by Dr. Giffin, Dr. Chesley and Governor Stassen.

Recent figures from Meeker County indicate that somewhat more than one-third of the population of the county has already been tested and eight cases of active disease have been discovered and are under treatment. The physicians of the county are carrying on the program without remuneration, but x-ray films have been provided by the State Medical Association.

It is understood that the next county to receive the certificate of accreditation will be Murray County with the ceremony likely to be held at the time of the Murray County fair. Stevens County is the fourth county to qualify for the award so far as death rates are concerned. Testing of senior students of the county is now under way there.

It would seem that the Meeker County experiment will prove the practicability of an ambitious method for detecting every active case of tuberculosis in each county and the eventual elimination of the disease from every county and state in the union. The task does not seem insurmountable.

Plan to attend the meeting in Duluth.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics

of the

Minnesota State Medical Association

George Earl, M.D., Chairman

WAR AND STATE MEDICINE

It is inevitable that a large number of physicians, especially younger physicians, will be in the armed services in the next few years.

That means, obviously, that the men who remain will be fewer, older and much busier than ever before.

It does not mean, however, that these same older, busier men may forget all about their economic and social responsibilities on the theory that they serve enough who diligently practice medicine.

The fact is that those who remain in civilian life must be doubly vigilant to see that, in spite of the burdens and demands of the times, the men and women at home do not suffer for lack of medical care.

Government has extraordinary powers these days and neither legislators nor people will patiently endure maldistribution of services, even when the situation is caused by wartime demands, if they can correct the matter by taking over medical services.

Physicians who cherish the rights and privileges of private practice and who see in state medicine a first-rate menace to standards and progress, will redouble their efforts to avoid any cause for government action.

It is clear to all students of the situation that, right or wrong, the burden of proof is on the medical profession. If the doctors come forward quickly and in sufficient numbers to fill the needs of the armed forces and if, at the same time, the older men are superhumanly watchful to see that all actually essential civilian needs are met, then it will be difficult even for a government disposed toward subsidies to take any radical action toward the establishment of government medicine.

MR. ALTMAYER RESPONDS

Observers in Washington do not believe that the plan for expanding functions of the Social Security system to include hospitalization and other benefits has been dropped.

It is stated in some quarters, on the contrary, that the legislation sketched by the Social Security board will be introduced as soon as the general revenue bill is adopted.

The chief purpose will be to impose an additional pay-roll tax which will raise two billion dollars in increased revenue. Hospitalization is more than likely to be included among the increased benefits which are to be offered as justification for the heavy rise in the tax.

Hospital executives and hospital service plan officials are not the only people who will be vitally interested in the outcome of this new method of fund raising.

See as First Step

Medical men also see in the plan a first, easy stage toward new billions to be raised on the still more attractive justification of allowances toward medical care. Also they see, with the hospital executives, a serious threat to the voluntary hospital system and particularly the thriving new plan of group hospital insurance.

Observations by Dr. S. S. Goldwater, president of Associated Hospital Service, New York City, on the new proposal of the Social Security Board were reprinted in these columns last month. Following are excerpts from a reply from Mr. A. J. Altmeyer, chairman of the Social Security Board, which appeared in a communication to the *New York Times*:

Inclined to Limited Plan

"Our studies have recognized from the start," says Mr. Altmeyer, "that hospitalization payments could take different forms but have not led to any final conclusions. At least two main types have been considered. The social insurance system could guarantee to insured workers and their dependents whatever hospi-

tal service may be necessary and pay the hospitals a fair reimbursement from insurance funds. Under a more limited plan the insurance system would pay the insured workers and their dependents a fixed cash benefit in partial reimbursement for each day of hospital care received up to a specified maximum in any one year. . . .

"The Social Security board has been inclined to recommend a plan of the second type. The benefit might be a minimum of \$3.00 a day or some other appropriate amount, in partial reimbursement for hospital service. For this program, as for social security programs generally, the objective would be to provide a minimum basic protection which many people would wish to supplement through other measures.

"The beneficiary, of course, might have the right to assign the benefit to the hospital which furnished the service so that the insurance system would make the payment directly to the hospital; or he might even assign his benefit to a voluntary hospital insurance plan to which he is a contributor. . . .

Would Cover Dependents

"It is quite true that the board has considered the level of benefits which should be provided by a contribution of one-half of one per cent by employer and worker. It should be pointed out, however, that the benefits considered would cover dependents of insured workers as well as the workers themselves and also retired workers and their dependents and survivors of insured workers who had died. This makes the protection much broader than is commonly found under similar programs. . . .

"As I have pointed out, social insurance benefits in general are designed to provide the worker only a basic minimum compensation for a risk . . . of course there is nothing final about the \$3.00 which has been mentioned. . . .

"It was recommended as an alternative recently in the *New York Times* that the 'Social Security Board could hardly do better than to permit the (American Hospital) association to extend its New York Community Ward Plan throughout the country leaving the local hospitals to make proper adjustments.'

"However, as you are no doubt well aware, the voluntary hospital insurance systems have recruited their subscribers in the main from economic groups well above the neediest. If these neediest groups are to be reached and served by any such plans it would probably be essential to follow the *Times'* other suggestion that 'private enterprise should be given the opportunity with federal financial aid to carry on the work the President has in mind.'

"Less Cumbersome"

"A subsidized plan such as this seems to suggest would probably prove less satisfactory to all concerned, less adequate and more cumbersome than the sort of plan the Board suggests which contemplates that the federal government will provide minimum protection, only, to the mass of wage earners and leave the remainder for the individual and for private asso-

ciations to cover in any way and to any extent that seems desirable and feasible.

"It is our reasoned conviction that such a program would not interfere with the development of voluntary plans but would result, as in the case of old age and survivors' insurance, in stimulating greater efforts to meet the remaining needs."

INTERPROFESSIONAL MEETING

Physicians, dentists, pharmacists from ten nearby counties met at St. Cloud under auspices of the Committee on Interprofessional Relations April 23 to talk over mutual problems and interests.

Nursing problems bulked large in the discussions and papers.

Dr. J. F. Du Bois, who opened the program, called upon all of the professions represented there to present an allied front.

"In Washington," he said, "there is a complete set-up for socialized medicine. There will be many doctors who, at the end of the war, will have no particular place to go and who can be readily shoved into government positions.

"We must be militant and let the public know that the ones to suffer from state medicine will be the public.

"Legislation must be watched. We must get each other's point of view and we must always remember that once the public is aroused, legislators have to act whether for good or evil. Anything can happen at the opportune time—and the opportune time may well be at the end of the present conflict."

Mr. J. B. Slocumb, secretary of the Minnesota State Pharmaceutical Association, appealed to the doctors to be ready to prescribe substitute drugs if the preparations originally ordered are not available.

Stocks of chemicals are becoming scarce in many instances; in others they are impossible to secure entirely, he said. Substitutes will have to be used.

Miss Louise Newcombe, president of the Minnesota State Board of Nurses' Examiners, gave a comprehensive explanation of the nurses' shortage which exists everywhere at the present time.

It is true, she said, that student enrollment has increased 22 per cent since January, 1927. Also graduate registration has increased in the same period by 47.3 per cent. Public health nursing has grown by a total of 4,000 new nurses and industrial nursing has increased by 1,000. But

there have been many inroads. Airlines and passenger trains have taken a considerable number. Hospital regulations providing for eight-hour duty have decreased the number of nurses available. Lastly and most important of all are the demands of the armed services, the Red Cross and government services.

"The army requires six nurses for each 1,000 men, the Navy three," Miss Newcombe said. "The Army Nurses Corps needs 10,000 additional nurses by July 1.

"To supply this need and offset the shortage, increased enrollment of students is not enough. Refresher courses are being given to retired nurses and ward aides, Red Cross volunteer aides and auxiliary hospital workers are being trained. In Minneapolis a nine months' course for practical nurses is offered by Vocational and Franklin schools. About one hundred are graduated yearly. Since July, 1941, the Federal government has allocated \$1,800,000 for nursing education."

Joint committees of physicians and nurses are studying the nursing situation in Minnesota in an attempt to meet the war demand, to maintain standards and to provide for needs of rural hospitals and rural communities.

NURSES NEEDED

Attention of all physicians has been called by Miss Laura A. Draper, chairman of the Student Nurses' Recruitment Committee, to the great need for well-qualified girls in the schools of nursing.

Before the war began the supply of nurses about met the demand, according to Miss Draper. As soon as war was declared the need increased sharply and it will continue to do so in direct ratio to the increase in the armed forces.

In Minnesota several schools have reported fewer than the expected number of applicants for the spring classes and a number of directors already state that applications for fall classes are falling short of the number customary at this time of year. In other parts of the country, furthermore, the need seems to be even more acute than it is here.

Many schools are expanding their facilities so as to be able to train larger classes and, though admissions may be closed in some individual schools, in general applicants do not meet the need.

Girls who enter nursing should be between eighteen and thirty years old. They should have good health and should have graduated in the

upper one-third of their high school class or have maintained a "C" average in college. The cost is generally between \$200 and \$300 for the three years' training.

Physicians are often consulted about nursing as a profession and about selection of training schools. It is the hope of the committee that they will make a special effort in view of the need, to interest girls of high caliber in the nursing profession.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

J. F. Du Bois, M.D., Secretary

Roseau District Court Grants Permanent Injunction Against Unlicensed Chiropractor

Re: State of Minnesota vs. K. H. Luross, also known as Knute H. Luross

In a case of far reaching importance, and one that establishes a precedent in the State of Minnesota, the Hon. Oscar R. Knutson, Judge of the District Court of Roseau County, Minnesota, made an order on April 9, 1942, granting a writ of injunction permanently restraining and enjoining the defendant Knut H. Luross

"from practicing healing in the State of Minnesota, including the practice of Chiropractic, until such time as he shall have been duly and regularly licensed to practice said healing in accordance with the laws of the State of Minnesota and until he shall have procured a certificate of registration in the basic sciences, and from advertising or in any way representing to the public that he is qualified or authorized to practice healing or to practice Chiropractic as defined by the laws of this State or from diagnosing, or attempting to diagnose, or treating, or attempting to treat, any of the diseases, maladies, afflictions or ailments of the human body."

On April 17, 1942, judgment was entered pursuant to the Court's order.

The action was brought in the name of the State of Minnesota for and in behalf of all the people, by the Attorney General, the Hon. J. A. A. Burnquist, R. F. Merriam, Special Assistant Attorney General representing the Minnesota State Board of Chiropractic Examiners, and Bert Hanson, County Attorney of Roseau County. The State alleged that the defendant was engaging in the practice of healing as a chiropractor in Roseau, Minnesota, without a basic science certificate and without a chiropractic license. The State also alleged that on March 12, 1936, the defendant had been convicted in the District Court of Polk County, of practicing healing without a basic science certificate and had been sentenced to serve a term of six months in the Polk County jail, the sentence being stayed and the defendant placed on probation; that thereafter the defendant moved from Fosston, Minnesota, to Roseau, where he continued to practice as a chiropractor, resulting in his arrest in the fall of 1941, for practicing healing contrary to law. The Court in its conclusions of law found that it is unlawful to practice healing in the State of Minnesota without first obtaining a certificate of registration in the basic sciences; that the defendant was practicing the art of healing in the

State of Minnesota, and that the defendant has no such certificate of registration in the basic sciences. The Court also found that to so practice in violation of law constituted a public nuisance and that the State of Minnesota was entitled to a permanent writ of injunction forever restraining and enjoining the defendant from engaging in such practice, in any manner, until he was properly licensed.

Judge Knutson, in a memorandum attached to his order, stated:

"By enacting laws requiring such license as a prerequisite to practicing the art of healing our Legislature has established the public policy that it is injurious to health to permit anyone to practice without a license. If these laws are to have any effect, anyone who has not shown himself qualified by passing the required examination must be prevented from so practicing. How else can this be done than by an injunction? That the penal provisions of the law are ineffective has been effectively demonstrated by the defendant himself. He was arrested, tried and convicted of violating this law on the twelfth day of March, 1936. He was sentenced by the Court to be confined in the County Jail for six months and the sentence was suspended and he was placed on probation. Thereafter he again engaged in the practice of the art of healing at a different location. He was again arrested in the fall of 1941 and successfully evaded trial at the Fall Term of Court in Roseau County. . . Our legislature has enacted laws intended for the protection of the public in prescribing certain preliminary tests of qualification before authorizing anyone to engage in the practice of the art of healing. The public is entitled to be protected from one who has not shown himself to be qualified, and until he has passed the examination required by law and procured his license to engage in the practice of the art of healing, it must be presumed that he is unqualified and unskilled and a menace to public health and safety."

Notwithstanding the fact that Judge Knutson's order establishes a precedent in the State of Minnesota, it would seem that the Court's order is in accordance with the facts and based on sound reasoning. It has been said that the defendant will take an appeal to the Supreme Court of Minnesota. We hope that he does so for it will settle a much discussed question in Minnesota, and there is every reason to believe that Judge Knutson's order will be sustained.

FLUORINE ACCUMULATES LIKE LEAD IN HUMAN BODY

Fluorine accumulates like lead in the human body when too much is absorbed, according to Dr. Willard Machle and E. J. Largent of the University of Cincinnati.

This report was made to the meeting of the American Association of Industrial Physicians and Surgeons and the American Industrial Hygiene Association in Cincinnati.

When increased quantities of various fluorides were added to the diet there was increased absorption and retention. In every case about half the amount of fluorine was absorbed and stored, regardless of how much was taken in. Normally about one milligram of fluorides is absorbed by a person on normal diet. This amount is passed off, but if more than two milligrams are taken in per day, the chemical begins to accumulate, particularly in the bones.

Commonest form of fluorine poisoning is mottled enamel of the teeth which occurs where the element is present in drinking water.—*Science News Letter*, April 25, 1942.

I'M IN THE NAVY NOW

LIEUT. COMDR. EDWARD DYER ANDERSON,

MC-V(S), USNR

Minneapolis, Minnesota

I have been in the Navy for about two months and there have been so many new experiences and so many adjustments to make that I think it may be of some interest to those of you who are going into Medical Corps of the Navy to hear of some of the things you are going to meet and the reactions you are likely to have.

In the first place there is the tremendous decision you have or are making in regard to whether you should leave your practice at home and join the Navy. If you have made the decision and have sent in your papers, you then have that long interval of several weeks during which you feel suspended in mid-air while you wait to find out whether you are accepted or not. During this time you find it extremely difficult to carry on your regular work and you stay awake nights wondering what you will do with your family, your home and your practice and how you will meet your insurance payments. Then you can't help but wonder what will happen to you and your family after the war is over. You feel, and undoubtedly correctly so, that if the war lasts two or three years, your practice will be gone and you will have to start all over again.

Finally your commission and your orders arrive and then you have three or four days of hectic existence. There are bills to be paid, final arrangements to be made and friends and relatives to say goodbye to. The result of this six to eight weeks before you go, is that you leave tired, but keyed up, tremendously excited and pretty much scared. You have a feeling of wanting to help your country and all it stands for, and you want to do the best possible job you can. You also feel quite important. You are leaving home at considerable sacrifice, financially as well as personally. Your friends and patients have all rallied around and told you how much they will miss you. Now the Navy has called you and you can't help but feel that it is because they have a particular need for you, personally. You are scared, because you have always heard or thought that the men you will meet and who will be your superior officers, will be hard-boiled old sea dogs, who are arbitrary, unreasonable and ready to bawl you out for every deviation from the rules, regulations and customs of Naval Regime.

The result of all this is that you arrive at your assigned station with a feeling which is a mixture of apprehension, excitement and resolve to jump right in and do a grand job of practicing medicine. You feel as if you could do an unlimited amount of work and you are sure that the Navy can hardly hold out until you get there to do it.

And now the surprises begin to come, one after another. The first one you meet is that you are going to be associated with a grand group of men. The regular Navy doctors, including your superior officers, are

doctors just like yourself and your doctor friends at home. They treat you with courtesy, kindness and helpfulness. They make every effort to make you feel at ease and to help you in any way they can. In other words, they are gentlemen, and they treat you as one. I am convinced that one of the traditions of the Navy is that they assume that every one from the apprentice seamen up, is a gentleman until he proves himself otherwise. Also you find that the majority of the doctors now in the Navy are reserve officers like yourself, who either have or are going through the same experiences that you are and it gives you a bond that draws you closer together.

For the first few days you are busy running around filling out papers, getting on the payroll, ordering new uniforms, arranging to get your allowance for travel and uniforms, and finding a place to live. The excitement of being in a new place, the large number of men in uniform, the big crowds, the saluting, the pride of walking around in your new uniform all tend to keep you keyed up to a new high.

And then the bubble breaks with a bang. You are raring to go, and do the best work you ever did. The government wanted you and brought you here to use your particular talents (and in your own mind you are convinced they are considerable). And all of a sudden you find yourself with nothing to do, no particular place to sit, no office of your own, and you sort of stand around feeling like a lost soul wondering why you left the busy practice where you were wanted and appreciated, to come to a place where they don't seem to realize how really good you are, and where they don't seem to need you. On top of this, by the time the original thrill is gone, you are lonesome for your family, you can't find a decent place to live and altogether you feel lower than a snake. This state of mind lasts for a few days and then you find that gradually the clouds lift. They do find a place for you, and you have a job to do. It may, and probably is, entirely different from the type of work you did at home. Nevertheless you are surprised to find that you enjoy it and that it is good for you to do something different, and you are pleased to find that you can do it. You are beginning to make some friends among the other men, and you feel more and more at home. Inside of a couple of weeks you begin to feel like an old-timer, and you can answer questions and help the new man that comes in. You are still frightfully green, but nevertheless you are beginning to fit into your niche. And then you begin to realize that with an organization as big as the Navy the only way it could work efficiently would be to have each man a part of a large pattern. The Navy can't be run on the basis of finding a place that would just suit you. They put you wherever they can use you, and expect that you will do your best job, whatever it may be. The surprising thing is that after a while you not only don't resent being just a cog in a vast wheel, but you actually enjoy it, and feel a great pride in being given the opportunity to help in keeping the wheel turning. As each day goes on you find yourself more and more proud of the Navy. One might say that although I may feel this way now, that six months

or a year or five years from now, I may change my mind. Possibly so, but I don't believe it. I am firmly convinced that one's respect and pride in the Navy will continue to grow, as its personnel, because of tradition, training and character, are bound to make one proud to be one of them. I'm in the Navy now and I'm proud of it.

MARINE CORPS ENLISTMENT

Requirements for enlistment in the United States Marine Corps have been widened so that men previously ineligible to enlist can now qualify, according to Capt. W. L. Harding of the Minneapolis recruiting office, in charge of this district.

Especially qualified men between the ages of 30 and 33, and men varying not more than 1 inch from the present height requirements of 5 feet, 4 inches, to 6 feet, 2 inches will be considered for enlistment. Minimum age for enlistment is seventeen.

In addition, applicants wishing to enlist in the Marine Corps can now do so *immediately*, without any waiting period. They may still enlist even though they have been called for induction by the army.

Applicants may enlist in either the regular Marine Corps or the Marine Corps reserve. Enlistment in the regulars is for four years; in the reserves, for the duration of the war. Choice is up to the applicant, and both branches provide identical pay, training, assignment to duty and chances for promotion.

Further information may be obtained at the Marine Corps recruiting offices in room 172, Federal Office building, Minneapolis; room 113, Old Postoffice Building, Saint Paul; 6 Robert Street, Fargo, N. D., and in the postoffice buildings in Duluth and Albert Lea, Minn.; Minot, Bismarck and Grand Forks, N. D., and Aberdeen, Sioux Falls and Rapid City, S. D.

TREATMENT OF CARRIERS MAY PREVENT DYSENTERY

Dysentery outbreaks in Army camps and in civilian institutions such as hospitals and prisons may be prevented by one of the newer sulfa drugs, sulfaguanidine, Dr. Lowell A. Rantz and Dr. William M. M. Kirby, of San Francisco, suggest (*Journal, American Medical Association*, April 11).

In nine out of eleven patients, ten of whom were regarded as healthy carriers of dysentery, sulfaguanidine treatment banished the dysentery germs, the San Francisco doctors report. As a result, the patients were no longer disease spreaders.

The healthy carrier of dysentery germs is probably the source of most cases of sporadic infection and if working in the kitchen of a camp or hospital may be responsible for serious outbreaks of the disease. If the sulfaguanidine treatment lives up to its present promise it should be a valuable aid, the physicians state, to the control of the spread of bacillary dysentery.—*Science News Letter*, April 18, 1942.

OCCUPATIONAL DERMATOSES

There are some important considerations in the treatment of acute dermatitis which should be brought to the attention of all physicians who see and treat industrial dermatoses. Loss of valuable time and future effectiveness of the individual may be prevented by following a few simple principles.

It must be emphasized that many cases of acute dermatitis do not require a specific treatment and if the patient is removed from the irritant and the treatment is of a mild soothing type and not irritating in itself the condition will be healed in about two weeks' time. Therefore, a specific treatment is not as important as management.

Treatment Should Be Mild

A dermatitis which does not respond to a given treatment and is steadily becoming worse should always be treated with a milder form of treatment and not with a stronger treatment. In addition to damage of the involved part, strong treatment may also disseminate the condition and produce sensitivity of distant parts. Whenever a dermatitis does not respond to a given treatment, the treatment and not the kind of dermatitis should be searchingly examined as the cause of the spreading.

Allergic Patients Sensitive to Chemicals

Patients who possess allergies are notoriously sensitive to chemical applications and may acquire sensitivities to drugs after they have been applied for a short while. This is strikingly demonstrated in the case of infantile eczema where the initial response to an ointment may be good only to see exacerbation with continued use and decided aggravation with increased strength. If then a change is made to a much milder preparation, healing often takes place.

I believe that all physicians should be warned that industrial dermatoses should be treated only with mild astringent solutions or very sim-

ple zinc pastes and that the source of irritation should be removed if possible and that the danger of producing general sensitivity should never be lost sight of.

D. D. TURNACLIFF, M.D.

WORKERS' HEALTH AND WAR PRODUCTION

Health programs in industry definitely reduce sickness and absenteeism, according to a résumé of reports from 234 companies made by the National Association of Manufacturers last year. An average reduction of 29.7 per cent in absenteeism was reported as a result of industrial health services. The saving exceeds the cost of health services to the employer.

"The estimated cost of a health program for a 500 man plant is \$13.46 per employe per year, or a total of \$6,730," the association points out in this report. "An estimate of savings and losses to industry in proportion to the extent of medical programs, made by the U. S. Public Health Service, revealed one and one-half times the average daily wage as the potential loss to the employer on account of absenteeism. Reductions of 47 per cent in accidents and occupational diseases and 28 per cent in absences, as reported for the average 500 man plant in the National Association of Manufacturers' study, would, on this basis, result in a saving to the company of \$12,341 per year, assuming an average daily wage of \$5. Deduction of \$6,730 for medical costs leaves a net saving to the company of \$5,611 per year while the saving in wages to the employes amounts to \$6,300."

The conclusions to be drawn in wartime from these studies are obvious.

Could Build Battle Ships

"Even if only 10 per cent reduction in days lost annually from illness and injury in industry were brought about" said a recent editorial in

(Continued on Page 495)

MINNESOTA STATE MEDICAL ASSOCIATION

EIGHTY-NINTH ANNUAL SESSION

June 29, 30 and July 1, 1942

The Armory, Duluth, Minnesota

Registration will open at the Armory, Monday, June 29, 8:00 A.M. Advance registration may be made at the Hotel Duluth on Sunday, June 28.

Scientific sessions will be held in two sections simultaneously at the Armory.

Luncheons.—Twenty-two Round-table Discussion Luncheons have been arranged for Tuesday and Wednesday, June 30 and July 1, at the Hotel Duluth. Tickets must be purchased in advance for these luncheons. Lists of subjects and leaders are printed in this program and on reservation cards mailed with the program. Attendance at each luncheon is limited to 25 and late-comers will be accommodated according to their choice if limits have not already been reached. Tickets 75 cents.

Annual Banquet.—The annual dinner for members, guests and their wives, will be held at the Hotel Duluth, Tuesday evening, June 30, at 6:30 p.m. Anton J. Carlson, Chicago, Professor of Physiology, University of Chicago, and Colonel F. W. Rankin, Lexington, Kentucky, president of the American Medical Association, will be banquet speakers. Tickets \$1.50.

Night in Bohemia.—All convention visitors and their wives will be guests of the Minnesota State Medical Association and the St. Louis County Medical Society at an informal party to be held Monday night, June 29, at the Northland Country Club. There will be dancing, Bohemian music, and entertainment.

Guest Speakers.—In accordance with an established precedent, several societies are sponsoring visiting speakers for this meeting. We are indebted this year to the following societies:

The Minnesota Radiological Society—Speaker, A. C. Christie, Washington, D. C., who will deliver the annual Russell D. Carman Lecture in radiology.

The Northern Minnesota Medical Association—Speaker, A. J. Carlson, Chicago.

The Northwest Pediatrics Society—Speaker, A. L. Hoyne, Chicago.

The Minnesota Academy of Ophthalmology and Otolaryngology—Speakers, F. H. Haessler, Milwaukee, and J. R. Lindsay, Chicago.

Minnesota Academy of Ophthalmology and Otolaryngology.—The Academy will hold an open meeting in connection with the convention on Wednesday, July 1, 2 to 4 p.m., in the Duluth room at the Armory. Clinics in eye, ear, nose and throat have also been arranged at St. Luke's Hospital, Wednesday morning, from 8:30 to 10:30 a.m. A luncheon sponsored by the Academy will be held Wednesday noon at 12:30 at the Kitchi Gammi Club. Tickets \$1.00. Clinics, luncheon and afternoon meeting are open to all convention visitors.

Nutrition Conference.—A special conference on Nutrition has been arranged for Tuesday afternoon, June 30, 2 to 5 p.m., in the Duluth room. Members and others especially interested in nutrition are invited to attend.

Industrial Health and Safety Conference.—A conference on Industrial Health and Safety will conclude

the regular convention program, Wednesday afternoon, July 1, 2 to 4 p.m. Plant superintendents and safety engineers from Duluth industries are invited to attend this session.

Medal.—The Southern Minnesota Medical Association will present its annual medal for the best scientific exhibit presented by an individual physician at this meeting. Presentation will be made at the banquet Tuesday evening, June 30, at the Hotel Duluth.

Fifty Club.—This year the Council of the Minnesota State Medical Association takes pleasure in the inauguration of Minnesota's "Fifty Club," made up of members who have been in practice in Minnesota for fifty years or more. Presentation of appropriate lapel buttons to those who reach a half century of service will be a feature of all future annual banquets of the Association. The first will take place Tuesday night, June 30, in connection with the eighty-ninth banquet at the Hotel Duluth. Fifty-year candidates will be honor guests of the Association on this occasion.

Medical Women's Luncheon.—A luncheon meeting for all women physicians will be held at the Hotel Duluth, Monday, June 29, at 12:15 p.m. Reservations for this luncheon should be made direct to Dr. Selma C. Mueller, president, Minnesota Branch, American Medical Women's Association, 915 Medical Arts Building, Duluth.

All-Alumni Get-together.—University of Minnesota Alumni will hold their annual reunion at a cocktail hour to be held at 5:30 p.m., Tuesday, June 30, in the Arrowhead Room, Hotel Duluth, before the Annual Banquet. All University alumni are invited to attend. Russell J. Moe of Duluth is chairman of arrangements.

Reunion, Class 1902.—The Class of 1902 will hold a fortieth anniversary dinner Monday, June 29, at 6 p.m. at the Hotel Duluth. Reservations should be made with E. A. Meyerding, 11 W. Summit Ave., Saint Paul.

Woman's Auxiliary.—Wives of physicians attending the meeting may secure programs of the business and social sessions of the Woman's Auxiliary at the Women's Registration Desk in the lobby of the Hotel Duluth. All visiting women are cordially invited to attend the special events arranged by hostesses of the St. Louis County Medical Auxiliary. Among these is a tea Monday, 3:30 p.m. at the Duluth Women's Club. The Annual Meeting and Luncheon to be held Tuesday, June 30, at the Northland Country Club, are open to all Auxiliary members. Out-of-town members will be guests of the St. Louis County Medical Auxiliary at a Round-up Breakfast to be held Wednesday, July 1, at 10 a.m. at the Hotel Duluth.

Golf.—The annual Golf Tournament of the Minnesota State Medical Association will be held Sunday, June 28, at 1 p.m. at the Northland Country Club. Attractive prizes have been donated. All medical golfers are urged to enter. Registrations should be made in advance on the enclosed card to C. O. Kohlbray, Duluth, for the tournament and the buffet dinner at the club at 6 p.m.

In Memoriam

Herman Burgess Cole

Dr. Herman B. Cole of Redwood Falls died on March 29, 1942, at the age of sixty-nine.

Dr. Cole was born in East Hamburg, New York, December 6, 1872, the son of Nelson Wesley Cole and Josephine Viola Blackmer.

After receiving his medical degree from the University of Buffalo, New York, in 1896, he practiced at Hamburg, New York, until 1897. He was married December 8, 1896, to Ella Mae McHugh of Buffalo.

Dr. Cole practiced from 1897 to 1918 in Franklin, Minnesota, except for two years spent at the New York Postgraduate Hospital from 1907 to 1909. From 1918 until the time of his death he practiced in Redwood Falls, associated with Dr. T. E. Flinn and Dr. John Gordon Cole, his son.

He was a member of the Renville County Medical Society, the Minnesota State and American Medical Association, the Civic and Commerce Association of Redwood Falls and the Odd Fellows.

Besides his wife, Ella M. Cole, Dr. Cole is survived by five children, Mrs. F. L. Bell, Milwaukee; B. L. Cole, Seattle; Mrs. Audrey Corbett, Redwood Falls; Richard F. Cole, army medical corps; and John Gordon Cole, Redwood Falls.

Arthur L. Herman

Dr. Arthur L. Herman died April 24, 1942, at the age of forty-one.

Born in Minneapolis, Dr. Herman attended the public schools, graduating from West Side High School. He later attended the University of Minnesota, receiving the degree of B.Sc. and in 1922 his degree of M.D. He interned at the Minneapolis General Hospital in 1922-23, and subsequently practiced medicine and surgery in Minneapolis, being associated with Dr. George Eitel.

Dr. Herman was a member of the medical staffs of Eitel and Asbury Hospitals. His medical and general associations included The Hennepin County Medical Society, The Minnesota State Medical Association, The American Medical Association, Minnesota Pathological Society, The American College of Surgeons, Phi Beta Pi, Incus, Alpha Omega Alpha, I.O.O.F., The Interlachen Country Club and the Minneapolis Athletic Club.

David Jackson Jacobson

Dr. D. J. Jacobson of Bemidji died at Rochester, Minnesota, April 16, 1942, following a second heart attack. The first heart attack was suffered in Portland, Oregon, earlier in the month, while visiting his family there.

Dr. Jacobson was born February 2, 1891, at Des

IN MEMORIAM

Moines, Iowa. He received his medical degree from Drake University in 1913. He practiced at Des Moines from 1914 to 1923 when he moved to Russell, Minnesota. In 1927 he went to Blackduck where he practiced until 1938 and then moved to Bemidji.

Dr. Jacobson was a member of the Upper Mississippi Medical Society, the Minnesota State and American Medical Associations. He became a member of the Association of Military Surgeons in 1919 and the same year became a Reserve Officer in the United States Public Health Service, of which he was an active member during the first World War. He had been a member of the Home Lodge No. 370 A.F. and A.M. at Des Moines since 1912, having transferred to his local lodge in 1936. He also belonged to the Benevolent and Protective Order of Elks.

Dr. Jacobson is survived by his widow and two daughters Jolayne and Lynne; two sisters Roslyn and Ella of Minneapolis and two brothers Joe and Ben of Des Moines, Iowa.

William Wilmerding Moir

Dr. William W. Moir was born in the town of Bloomington on March 26, 1881, the son of Joseph and Agnes (Pond) Moir. His early schooling was obtained at the Minneapolis Public Schools where he graduated from Central High School. He attended the Medical School at the University of Minnesota, receiving his degree of M.D. in 1906 and for the next year was an intern at Asbury Hospital.

From 1907 to 1911 Dr. Moir practiced in Gilbert, Minnesota. Subsequently he returned to Minneapolis where he practiced general medicine and surgery until the time of his death. He attended clinics at the University of Vienna in 1926.

He was on the staff of Asbury Hospital and served as President of the staff in 1939. During the World War he served as Medical Officer of Ambulance Company No. 4, attached to the 31st Infantry, stationed near Vladivostock, Siberia.

Besides being a member of Hennepin County Medical Society, Dr. Moir was a member of The Minnesota State and the American Medical Associations. He was a member of Ark Lodge, A. F. & A. M., Phi Rho Sigma, the Lafayette Club, Automobile Club and the Simpson Methodist Church.

Dr. Moir died at his home February 3, 1942, being survived by his wife and three sons, one of whom, Wm. W. Moir, is a First Lieutenant in the Medical Corps of the United States Army.

Reuben Pennington

Dr. Reuben Pennington was born in Minneota, Minnesota, November 19, 1894. He graduated from the Minneota High School and subsequently attended the University of Minnesota where he graduated from the College of Dentistry in 1915. After practicing his profession at Minneota and at Glenwood, Minnesota, from 1915 to 1923, he attended the medical school of the University of Minnesota from which he graduated

in 1929. He interned at the Minnesota General Hospital from 1929-1930 and subsequently practiced general medicine in Minneapolis.

Dr. Pennington was a member of the visiting staff of Asbury Hospital and was on the staff of the University Students Health Service. He taught in the dental school of the University of Minnesota from 1930-1931. He was a member of the Hennepin County Medical Society, Minnesota State and American Medical Associations. He belonged to Delta Sigma Delta and was a member of Ark Lodge, A. F. & A. M. Dr. Pennington died February 25, 1942, being survived by his wife and one daughter.

INDUSTRIAL HEALTH

(Continued from Page 489)

The Journal of the American Medical Association, "this saving would equal the time required to build five capital ships, sixteen thousand tanks or nine thousand bombers."

As war production in the United States climbs and working hours are extended the question of fatigue and absenteeism also becomes acute in many plants.

Fatigue Is Problem

Careful British studies made during the last war showed that at three shell factories men working sixty-three and one-quarter hours per week lost 7 per cent of their time from sickness. The percentage diminished as the working hours decreased so that when the working week was fifty-four hours the lost time was only 4 per cent.

In American munitions plants where the working day was increased from nine to twelve hours, the rate of absenteeism increased from less than 6 per cent before the hours were lengthened to 9.3 per cent during the first year after the increase and to 12.2 per cent during the second year, thus showing the cumulative effect of longer hours.

The conclusion of British investigators, made on the basis of studies made during the last war and in this war, is that more than sixty hours a week leads to increased loss of time during work, increased absenteeism and illness. One day's rest in seven is found to be essential furthermore, and organized or enforced rest periods, particularly with an opportunity to take food during the rest period, assist in maintaining a high output level.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of April 8, 1942

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, April 8, 1942. Dinner was served at 7 o'clock and the meeting was called to order at 8 o'clock by the President, Dr. Martin Nordland.

There were 44 members present.

Minutes of the March meeting were read and approved.

Upon balloting, the following men were elected as candidates for membership in the Academy:

Dr. Francis Lynch.....	Saint Paul
Dr. J. B. Carey	Minneapolis
Dr. Walter Fansler	Minneapolis
Dr. L. H. Fowler	Minneapolis

The scientific program followed.

Dr. Yoerg, of Minneapolis read his Inaugural Thesis on "Cysts of the Urachus." Lantern slides were shown.

CYSTS OF THE URACHUS

OTTO W. YOERG, M.D.

Minneapolis, Minnesota

Cysts of the urachus, caused by incomplete closure of the allantoic canal, though uncommon, are frequent enough to occasion interest in a review of the literature. The condition probably occurs more often than the small number of reported cases would indicate.

Embryology and Anatomy

The urachus is a fetal relic. It is the remains of the allantoic stalk which in embryonic life extends from the cloaca into the umbilical cord. This canal gradually becomes occluded in early fetal life and forms a connective-tissue cord extending from the apex of the bladder to the umbilicus as the superior ligament, which lies anterior and is firmly attached to the peritoneum. Morris states that it assists in keeping the bladder up, especially in early life, so that the bladder is easily emptied and is allowed to enlarge in its freest directions.

The urinary bladder is of mesodermic origin and arises from the ventral portion of the cloaca, later forming a triangle continuing from the apex as the allantoic stalk to the umbilicus (Kantor). Bladder epithelium has been demonstrated in a urachus.

Luschka states that the allontois does not become a complete cord, but that small cavities may remain in the urachus. These cavities are called the Lacunae of Luschka and are found only at postmortem.

Pathological Anatomy

The normal process of embryonic closure of the allantoic stalk to form the urachus occasionally does not take place; instead a complete or partially patent urachus remains. When complete, a canal connects the bladder with the umbilicus, with the result that urine may escape at the umbilicus. McGregor states that this condition is usually associated with some obstruction of the outflow of urine from the bladder. He has had two such cases with obstruction at the prostatic urethra.

Cysts of the urachus can develop as a result of a disordered anatomy. They may be minute or large. A number of cases in which the cysts attained enormous size have been reported. Archibald states that the smaller cysts frequently show the remains of the longitudinal muscle coat of the urachus, being lined with transitional epithelium. The larger cyst walls are usually fibrous, and the lining is usually a single layer of flattened epithelial cells. The fetal urachus is lined with several layers of epithelium, and sections of the lumen may be occluded with cells.

Vaughn and Long are in substantial agreement as to classification. Long suggests a classification of four types for cysts of the urachus:

1. Those which communicate only with the bladder.
2. Those which communicate only with the umbilicus.
3. Those which communicate with both the bladder and the umbilicus.
4. Those which do not communicate with either the bladder or the umbilicus (blind type).

Vaughn has a similar classification and states that the blind type, closed at both ends, is the most frequent group encountered. Cysts of the urachus may occur anywhere along the urachus, but are more frequently found in the lower half.

Infection is present in practically all of the cysts that come to operation. Colon bacilli, streptococcus and staphylococcus have been reported. Many cases, however, show no bacteria on smear or culture. The mode of infection is not clear, but most observers feel that entrance through the lymphatics or blood stream seems plausible.

Cysts of the urachus can become malignant. F. Pendl reports a case of colloid carcinoma and states that Schwartz in 1912 reported the first case of primary carcinoma of the urachus. T. deWaard in 1939 reported two rare cases of cancer of the urachus.

John H. Long in 1927 reported a dermoid cyst of the urachus, definitely proved by microscopic section. Cullen in his "Diseases of the Umbilicus" states that dermoid cysts are rare and after reviewing the cases reported found only six to be definitely dermoid cysts.

Etiology

There appears to be no agreement as to why urachal cysts occur. Some believe that the Lacunae of Luschka enlarge to form the cysts. It would, however, hardly seem possible that these minute cavities could enlarge without a secreting lining. Although bladder epithelium does not have a secreting function, it is, of course, possible that epithelial lining may have changed its function and become secreting. An obstruction of the urine flow would account for the completely patent cyst, but could not produce the internal blind cyst, which is by far the most common type.

Diagnosis

Diagnosis of a urachal cyst is usually made at operation. A small or large tumor mass in the midline between the umbilicus and the symphysis pubis may exist for years without producing symptoms. Only when these cysts become infected is relief sought.

The usual symptoms of infection, such as fever, increase in white count, and an enlargement of the mass, which is usually firm and often tender and painful, should lead one to suspect a urachal cyst. Only about 15% show a discharging sinus at the umbilicus. Diagnosis of a patent urachus is not difficult as urine escapes at the umbilicus. It is, in fact, usually recognized in infancy. If an opening is present into the bladder and closed at the umbilicus, a cystoscopic examination is of value, but differentiation from a diverticulum of the bladder may be somewhat difficult. The closed or blind type, by far the most common, is also the most difficult of diagnosis. The condition has been confused with parovarian cysts, extopic gestation, tuberculous peritonitis, appendicitis, distended bladder and, when of considerable size, ascites. It should not be confused with a vitelline duct cyst, also a rare vestigial condition, as this type of cyst, though it occurs at the umbilicus, does not continue as a sinus toward the symphysis pubis. If the infected cyst has ruptured into the peritoneal cavity, peritonitis will further complicate diagnosis.

Archibald states that urachal cysts of moderate size are palpable below the umbilicus, sometimes slightly to one side of the midline as rounded tumors often moving more freely from side to side than up and down, and that movement of the tumor from side to side may produce an indrawing of the umbilicus.

Treatment

Various methods of attack in the treatment of urachal cysts are advocated. In some cases the cysts can be removed completely without entering the peritoneal cavity. However, if infection is present, the cyst will usually be firmly adherent to the peritoneum and a conservative procedure is advisable, consisting of incision, curettage and free drainage. It appears that many of these infected cysts so treated will heal permanently. If, however, the sinus should persist, excision of the cyst can be done more safely later, in the absence of acute infection, for it is usually necessary to enter the abdominal cavity to facilitate removal. In the patent urachus which connects with the

bladder, it is obvious that removal is necessary and that the opening in the bladder be closed.

Padovani and Dufour feel that if a resection of the cyst is done it is necessary to pass distinctly outside of the limits of the cyst in order to open the peritoneal cavity without trying to separate the cyst from the peritoneum, which would involve the danger of entering both the cyst and abdominal cavity and infecting the peritoneum with the septic contents of the cyst.

Review of the Literature

A study of the literature discloses that Lawson Tait, in an article published in 1883 in the *British Gynecological Journal*, gave the first clear picture of this condition. He reported twelve cases. Weiser made an extensive review of the literature up to 1906 and collected eighty-six cases, to which he added three of his own. In the eighty-six cases reported only nine were patent, seven were external blind, eight internal blind and forty-six blind. Sixteen could not be classified. He found few statistical papers. From his article it appears that Hoffman, in 1870, Wolff in 1873, and Atlee in 1873, had given first reports of cysts of the urachus. Next, Wutz, in 1883, analyzed all alleged cases diagnosed clinically or at autopsy, said most of them had been mis-diagnosed or had questionable symptoms, and felt that there were definitely no clinically important urachal cysts reported up to that time.

Doran also tried to break down the diagnosis of cases and in a measure agrees with Wutz.

Tait, it appears, was the first to make a diagnosis of urachal cysts before operation and only a few have made claim to prior diagnosis since then. F. Byron Robinson has reported four additional cases of Tait's and two of his own. Weiser's three cases have all been large cysts, two in women and one in a man. He made a complete removal of the cysts, and all these patients recovered.

The data on the condition suggest that it is rarely encountered. Weiser states that much of the history in the eighty-six cases up to 1906 was meager and questionable; twenty-one of these reported were males, fifty-eight females and in seven, sex not stated. He made the deduction that urachal cysts were most common in middle life, for half of the cases in which age was given occurred between the ages of twenty and forty. He deduced that they were more frequent in women than in men. Hugh Young states that only three cases were found in 12,500 admissions to the Brady Urological Institute.

Kantor, in the *Annals of Surgery* in 1939, gave a résumé of all cases reported from 1907 to 1936, to which he added two cases of his own. He found thirty-six cases. The records in this more recent series are most complete, as would be expected because of more modern methods in diagnosis. Roentgenology, contrast media and the cystoscope have made it possible to make a preoperative diagnosis more often. In this series of thirty-six cases, twelve were diagnosed preoperatively. Ages ranged from twenty months to sixty-nine years; average age, twenty-eight. The condition occurred in nineteen males and seventeen females, this in

contrast to earlier reported cases in which females predominated. Of these, thirty-two cases were in Group four, communicating with neither the bladder nor umbilicus. However, twenty-two of these were questionable, that is, could not be definitely placed in Group four. One case was a questionable Group three, communicating with the bladder and umbilicus or completely patent. Two cases were in Group 1, communicating only with the bladder. One ambiguous case was probably in Group 2, communicating only with the umbilicus. Definite infection was shown in twenty cases, eight cases were probably infected, and in eight

has always been well, but for the past two years had noticed a small lump just below the umbilicus. This mass had increased slowly in size, but had not been tender nor painful until ten days before admittance to the hospital. At that time the mass became much larger, with pain, which became worse on straining. At no time had there been a sinus or discharge at the umbilicus.

The patient was admitted to Northwestern Hospital on September 2, 1923, temperature 100°, pulse 80, blood pressure 140/90, leukocyte count 16,000, urine negative except for a trace of albumin.

General physical examination disclosed a normal individual except for an acutely inflamed swelling two inches in diameter in the midline of the abdomen below the umbilicus. A diagnosis of an incarcerated infected hernia (omental) was made, with possible Meckel's diverticulum.

Operation was done the following day under general anesthesia. An incision was made over the swelling, which was then the size of a small orange. A thick walled cavity was entered which contained a heavy mucoid pus, without offensive odor. On exploration of this cavity, it was found that a probe could be passed down the midline between the fascia and peritoneum. No omentum was recognized and no sinus could be found entering the abdominal cavity. The wound was drained and the symptoms subsided. Ten days later, a complete gastrointestinal study was done. This disclosed no connection of the intestinal tract with the abscess cavity. Smears from the contents of the cavity showed no bacteria and no growth on culture. The patient was discharged from the hospital sixteen days after incision of this abscess. Two months later the wound had healed and remained sealed for six months, when a small amount of the same mucoid drainage reappeared, but the wound healed readily and did not cause discomfort.

The patient was seen again in June, 1927, when a diagnosis of an acute retrocecal appendicitis was made, and an operation performed. A retrocecal appendix with an abscess was found. The appendix was removed and the abscess drained. At that time it was noted that no connection existed between the abdominal parietal wall and the intestinal tract. The patient recovered, and left the hospital four weeks after operation.

In June, 1930, seven years after incision and drainage of the abdominal wall abscess, the patient returned again, stating that the sinus at the umbilicus had opened and closed every few months in the past three years, but recently had opened and closed once a week. He stated he was otherwise well but was tiring of the annoyance of this persistent discharge. He again entered Northwestern Hospital on June 30, 1930. His temperature was 98°, pulse 65, blood pressure 148/98. The urine showed a trace of albumin but no pus. He was taken to the x-ray department, where the sinus was injected with lipiodol and anteroposterior and lateral films were made of the abdomen. The films disclosed a sinus extending downward in the median line toward the pubic area, and at the lower end of the sinus an enlargement about 1.5 inches in diameter was noted. The sinus and cyst cavity appeared to be just anterior to the peritoneum but with no evidence of any connection with the urinary bladder.

A diagnosis from the x-ray findings of an infected urachal cyst and sinus was made.

Operation was performed on July 1, 1930, under local anesthesia. The sinus was injected with methylene blue. To our amazement a black contrast media resembling india ink resulted from the incompatibility with the iodide. This was found later to be a much better media for contrast than the methylene blue itself. A catheter was then inserted into the bladder to obtain urine, which was found to be free from methylene blue, indicating that the cyst did not connect with the bladder. An incision was made in the midline, from the umbilicus to the pubis, and the old scar was removed. The

cases, no evidence was found of infection. Removal by excision was done in twenty-four cases, operation was reported difficult in five, and the peritoneum was excised in these five cases with cyst wall. Of those excised, sixteen were cured, five died of peritonitis, and one patient died of anesthesia. Incision and drainage were performed in twelve cases and all recovered. Nine were cured and two were improved, and later excised with cure. One case was not followed. In several cases the bladder was opened. Inadequate closure of the abdomen was encountered occasionally.

Kantor's two patients were a female child two years of age who was cured by incision and drainage, and a physician, aged 29. The cyst was drained but the sinus continued to discharge. Ten months later the cyst was excised, but convalescence was again complicated by continued drainage. Several months later x-rays disclosed a sinus extending to the right iliac region. An exploratory operation disclosed an old gangrenous appendix with abscess. Recovery was uneventful except for a persisting small fecal fistula.

Cases since 1936 have been reported by Garvin, A. Wylburt and J. C. Lacano Gonzaley, G. and R. Gayet, and Clavel and Cavillher.

Case Report

A.R.E., aged forty-six, married, construction superintendent, a vigorous, well nourished man, states that he

sinus was then explored and dissected out from the umbilicus downward. It was found to lie under the fascia and directly over the peritoneum to which it was firmly attached. After careful dissection the sinus was removed without entrance to the peritoneal cavity, down to the lower end, where it widened into a cyst-like

Fig. 3. Low power photomicrograph from cyst wall discloses a large amount of fibrous tissue with chronic inflammation, and blood extravasation.

cavity about 1.5 inches in diameter. The lower end of this cyst cavity appeared to end at the dome of the urinary bladder. The cyst was firmly adherent to the peritoneum and contained a broken down cellular debris, which was scooped out. Smears made of this material showed it to contain cellular debris but no bacteria.

It was found that removal of the cyst would require entering the abdominal cavity. Because we were certain that the cyst did not communicate with the bladder, we felt a more conservative course to be advisable. The cyst cavity was then curetted and treated with a 20 per cent silver nitrate solution. The upper wound was closed and a gauze packing used in the cyst cavity with a small penrose drain along the old sinus to the umbilicus. This drain was removed two days later.

Microscopic sections of the tissue disclosed inflammation and increase of connective tissue with round cell infiltration. An area of small square and columnar epithelium was found arranged in a row. These cells apparently were the remains of the cell lining of the cyst.

The patient's convalescence was uneventful and he was able to leave the hospital two weeks later. The packing in the cyst cavity was renewed every few days for a period of six weeks. The wound was fully healed in about two months.

It is now over eleven years since the operation and there has been no recurrence of symptoms. He has for the last three years supervised government construction in Alaska.

Summary

The urachus, a vestigial remnant, only rarely gives rise to pathological conditions. When disease does occur it is usually in the form of a simple cyst, but occasionally the cyst may be a dermoid. Cysts of the urachus

Fig. 4. High power microphotograph. Note dense fibrous wall and lymphocytic infiltration. An area is disclosed showing square type and low columnar epithelial cells arranged in a row which are apparently the remains of the cell lining of the cyst.

can become malignant. Several cases of carcinoma have been reported.

A cyst of the urachus may remain dormant for years, and only become of surgical importance when infected.

The cause of infection in these cysts is obscure, but its course is probably through the lymphatics or the blood stream.

Diagnosis preoperatively is difficult in the case of a large cyst as it must be differentiated from other abdominal tumors. In the smaller cysts diagnosis should be easier, but is probably overlooked because of its rarity.

Treatment of cysts of the urachus is either complete excision of the cyst or incision and drainage. It is evident that most of the men reporting cases are aware of the dangers of peritonitis when complete removal is attempted. This danger is obvious as noted in the thirty-six cases collected by Kantor, where a death rate of approximately 30 per cent occurred following excision, whereas in contrast, no deaths occurred when incision and drainage were practiced.

Conclusion

A review of the literature on urachal cyst is presented with a description of the anatomy, embryology, histology and pathology. The etiology, diagnosis and treatment are discussed from an analysis of various cases reported and the conclusions arrived at by the

men reporting their findings, and from the knowledge obtained from treating a case which is described in detail.

Discussion

DR. A. E. BENJAMIN, Minneapolis: I talked with Dr. Yoerg today about this case of his. I happened to remember I had one or two cases in the past and looking up the records found one rather interesting one. The patient was a woman 42 years of age. She had a very badly displaced uterus and this tumor was rather high in the abdomen. I could not make out that it was connected with the uterus at all. I decided to operate, and, when we got in, found this tumor was a cyst of the urachus. It did not open into the bladder or umbilicus and was not inflamed. After some exploring of the abdomen, I decided to dissect it out. I dissected out the whole urachus and cyst and then did a modified Gillian operation to replace the uterus. She made a very satisfactory recovery and has had no trouble since. The microscope confirmed our diagnosis.

The second patient whom I recall did not have much of a cyst but did have a long discharging sinus extending down to the bladder. This was cured by injecting nitrate of silver, as Dr. Yoerg did in his case.

DR. F. E. B. FOLEY, Saint Paul: Dr. Yoerg is to be congratulated on his excellent and comprehensive description of cysts of the urachus; and the Academy upon acquiring a general surgeon capable of such an erudite presentation of a urologic subject.

It is easy to recognize the obvious; to recognize the obscure marks clinical talent. Diseases of the urachus seem obscure only because of general want of famil-

ilarity with urologic subjects and, particularly, urologic embryology.

My first interest in diseases of the urachus was prompted by the New Zealand urologist, J. Campbell Begg, during a visit here several years ago. At that time Mr. Begg was making a comprehensive study and review of the subject, particularly with reference to tumors of the urachus. While in Rochester, he reviewed and analyzed all of the Mayo Clinic cases. While engaged in this study he was my guest and expounded at length on his then current interest. Later, he published a comprehensive paper on the subject which is generally regarded as authoritative. I was surprised that Dr. Yoerg did not refer to this publication.

Cyst formation is only one of the pathologic changes that affect this vestigial remnant. Lesions of the urachus may be classified under three groups: (1) inflammation (of which I have seen three cases); (2) cyst (of which I have seen two cases); and (3), neoplasm (of which I have seen one case).

There may be inflammation of the urachus without cyst formation or cyst not accompanied by inflammation. The inflammatory process usually extends to surrounding structures and presents as a palpable mass in the midline below the umbilicus.

The cysts and associated inflammatory change have been described by Dr. Yoerg.

The commonest neoplasm is adenocarcinoma.

Dr. Yoerg stated that diagnosis is usually made at operation, and that the first diagnosis was made by Tate, and since then there have been very few correct pre-operative diagnoses. My own experience and that of most urologists is strictly not in accord with these assertions. My own error has been not failure to recognize disease of the urachus but the error of making this diagnosis in cases of other lesions. A small papillary tumor in the vault of the bladder was erroneously diagnosed as a tumor of the urachus simply because of its location. With the exception of a few cases, correct diagnosis of diseases of the urachus is easily made. When a mass is palpable in the abdominal wall below the umbilicus, pathologic change in the urachus should be one of the first things considered. The next thing to consider is cystoscopy. By means of cystoscopy, most lesions of the urachus will be recognized. A localized area of inflammation in the bladder vault is usually an extension of inflammation from the urachus. A polypoid or papillary projection of the mucosa in this location may represent an inflammatory polyp or neoplasm originating in the urachus and projecting or extending into the bladder. The usual neoplasm is adenocarcinoma and needs radical excision. Purulent material exuding from a point in the bladder vault is usually the exudate from an infected urachus with or without cyst formation. Another pathologic condition which may be confused with this and differentiated with difficulty is a diverticulum of the bowel which has attached itself to and ruptured into the vault of the bladder. I observed one such case. There was profuse pyuria, the source of which was a small opening in the bladder vault. Further studies with contrast medium proved that the tentative diagnosis of infected urachus was incorrect and that, actually, there was a diverticulum of the bowel communicating with the bladder.

In the presence of a new and acute inflammatory process, preliminary incision, drainage and curettage may be appropriate—but will not be curative. In all of the cases I have encountered, the inflammatory process was of long standing and in all of these complete excision was successful. In at least one of these cases the peritoneal cavity was soiled with infectious contents but with no untoward effect. When the inflammation is of long standing, the patient has been well vaccinated and soiling of the peritoneum is well borne. Except in cases of sudden, acute inflammation of the urachus, I would be in favor of complete excision as only this will give permanent cure. In cases of

sudden, acute inflammation, possibly with abscess formation, incision and drainage, I should think, would be appropriate but should be regarded as a preliminary measure.

DR. PHILIP DONOHUE, Saint Paul: The urologist may encounter cases representing pathologic conditions of the urachus, and therefore is interested in the subject presented by Dr. Yoerg. My most recent clinical experience was in the case of a 22-month-old boy. This case illustrated the effect of urinary obstruction in the production of pathologic changes in the urachus. Dr. Begg, in his discussion of this phase of the subject, stated that the urachus communicates with the bladder in one-third of normal individuals. The communication may be recognized cystoscopically as a small papilla or indentation in the vault of the bladder. A fold of mucosa or a valve prevents urine from entering the urachus. If obstruction to the bladder occurs, the elevated intravesical pressure will be sufficient to overcome the valve, permitting the introduction of urine and bacteria with development of pathologic changes such as cysts and abscesses.

In the child referred to there was congenital urethral stricture, and large retention of urine in the bladder. The child's condition was poor, due to advanced hydro-nephrotic change and urinary infection, and immediate cystostomy was indicated. A poorly-defined mass was palpable in the abdominal wall over the distended bladder, and a pathologic condition of the urachus was suspected. The urachus was completely removed. The structure was separated from the peritoneum down to the bladder and then extraperitonealized. The suture line to close the peritoneum was T-shaped. The attachment with the bladder was divided and examination of the intact urachus after excision showed inflammation with abscess formation.

DR. YOERG, in closing: I stated early in my paper that urachal cysts probably occur more often than the small number of reported cases would indicate. This is borne out by the discussion here tonight.

Dr. Benjamin several days ago recalled two cases of probable urachal cysts in his practice, which he was kind enough to report here. The description of his cases fits the condition perfectly.

Begg's paper, referred to by Dr. Foley, is an excellent presentation on the subject. Most of the literature is made up of only case reports.

I agree with Dr. Foley that excision of the cyst is desirable. However, when acute infection is present, incision and drainage is safer. There should be no mortality when incision is performed. If a cure cannot be effected, the cyst can be excised later with much less chance of infecting the peritoneal cavity.

Dr. Donohue spoke of obstruction at the prostatic urethra, and the use of the cystoscope. Obstruction of the outflow of urine undoubtedly causes a back pressure which prevents the normal obliteration of the abdominal portion of the allantois, resulting in a patent urachus, as noted by McGregor.

I want to thank Dr. Gustav Schwyzer for his kind remarks.

The meeting adjourned.

E. V. KENEFICK, M.D.,
Secretary.

According to a survey made by Joseph N. Burroughs of Oakland, California, the birth of children to Rotarians has decreased rapidly since the days of our grandparents. "Present Rotarians," he says, "have an average of 1.71 children, compared with 4.74 for their fathers and 5.68 for their grandfathers."

WOMAN'S AUXILIARY

MRS. JOHN J. RYAN, *President*

Saint Paul, Minnesota

MRS. L. R. BOLES, *Publicity Chairman*

Knollwood, Hopkins, Minnesota

General News

A special meeting of the Auxiliary State Board was called by the president, Mrs. John J. Ryan, on May 7, 1942, in the Lowry Medical Arts Building, Saint Paul. At that time it was decided that the president-elect, Mrs. R. J. Josewski, Stillwater, should go as the delegate to the national convention in Atlantic City and read Minnesota's report.

Mrs. J. M. Reynolds, Minneapolis, chairman of the Revisions Committee, read the new constitution and by-laws for the State Auxiliary and an informal discussion followed. Others who had assisted on the committee were Mrs. E. V. Goltz, Saint Paul, and Mrs. Harold Wahlquist, Minneapolis.

Remember the State Medical Association convention in Duluth, June 29, 30, and July 1, 1942. Plan now for a little vacation then!

County News

Stearns-Benton—The Medical Auxiliary held its regular dinner meeting at the Hayes Hostess House in St. Cloud, April 23, 1942. Mrs. P. E. Barringer, president, presided at the business meeting. Mrs. William Friesleben, finance chairman, announced that the rummage sale and card party given in April had been quite successful.

Members reported that they have supported the Red Cross in many ways: Mrs. Karl Walfred is conducting a class in Home Nursing, with several members taking the course; others are taking courses in First Aid and Nutrition; many are doing sewing and knitting in their homes, Mrs. J. B. McDowell having one thousand hours to her credit in this work. There are still others who are working on the National Women's Defense Program.

The following Nominating Committee will present a state of officers at the next meeting:

Mrs. Karl Walfred, St. Cloud; Mrs. S. J. Raetz, Maple Lake; Mrs. J. J. Gelz, St. Cloud.

The program which followed included a review of the book "The Doctors Mayo" given by Mrs. John Gelz, and a review of the article "How to Relax" taken from *Hygia* and given by Mrs. P. E. Barringer.

Mrs. F. P. Frisch, Willmar, was a guest at the meeting.

Hennepin—The annual luncheon of the Auxiliary was held at 510 Groveland Avenue, May 1, 1942. Mrs. John Curtin, who has been a splendid social chairman, made the affair a grand finale for the termination of a fine Auxiliary year. Being May Day, there were gay pots of begonias at each place with huge boxes of pansies at the head table. Mrs. F. S. McKinney, president, presided. Eighty-six members were present, and

following the annual reports, a fine slate of officers was elected for next year. Mrs. Henry Quist expressed what everyone sincerely felt—the appreciation of having had such a very fine president in Mrs. McKinney for the past year—her good, fair leadership appealed to all!

The following are the newly elected officers:

President—Mrs. James Johnson
 President-elect—Mrs. Harold Wahlquist
 First Vice President—Mrs. J. M. Hall
 Second Vice President—Mrs. Willard White
 Treasurer—Mrs. Frank Bryant
 Recording Secretary—Mrs. Charles Merkert
 Corresponding Secretary—Mrs. R. F. Erickson
 Auditor—Mrs. Henry Quist
 Custodian—Mrs. E. G. Nylander

Mrs. J. C. Davis has been appointed Minneapolis commander of the Woman's Field Army of the Minnesota Society for the Control at Cancer. In this post, she recently conducted the sixth annual enlistment drive and educational campaign here.

Red River Valley.—The sixteenth anniversary of the founding of the Auxiliary to the Red River Valley Medical Society was recently observed when members of the Auxiliary gathered at the home of Mrs. M. O. Oppegaard for their annual business meeting, following a dinner session with their husbands.

Mrs. D. V. Boardman of Twin Valley, retiring president, presented a cake, flanked by sixteen candles, and members participated in a candlelighting ceremony honoring officers of the past years, and four charter members who are still active in the organization—Mrs. G. A. Morley, first president; Mrs. J. F. Norman, Mrs. O. L. Bertelson and Mrs. C. L. Oppegaard. A song was offered in tribute to the charter members.

Officers elected were: Mrs. W. G. Paradis, Crookston, president; Mrs. A. Shedlov, Fosston, vice president; Mrs. O. K. Behr, Crookston, recording secretary; Mrs. C. G. Uhley, Crookston, corresponding secretary; Mrs. C. L. Oppegaard, treasurer.

The Auxiliary voted a contribution to the American Field Army for the Control of Cancer and pledged its support to this organization in other ways.

Mrs. Shedlov won score honors at the bridge which followed the business meeting.

Ramsey.—Success is not achieved without effort! A great deal of thought and work were put into the recent successful teas given by Ramsey County Auxiliary.

The tea at the University Club, Saint Paul, in honor of the wives of physicians attending the American College of Physicians convention, was attended by a large number of women. Mrs. E. V. Goltz headed the committee on arrangements. It was a beautiful tea!

Presidents of all women's organizations in Saint Paul were invited to the Public Relations Tea given by Ramsey County Auxiliary. Mrs. Charles W. Wass, public relations chairman, with Mrs. L. W. Barry, were in charge of the event. Assisting her were: Mmes. E. C. Eshelby, C. Harry Ghent, Eugene E. Scott, William Heck, Henry VonderWeyer, Bernard O'Reilly, John A. Lepak, Joseph Bicek, and Herman Kesting. Presiding at the tea table were: Mrs. John J. Ryan, presi-

dent of the State Auxiliary; Mrs. Mark Ryan, president of Ramsey County Auxiliary; Mrs. George A. Williamson, president-elect of Ramsey County Auxiliary; and Mrs. Carl B. Drake, wife of the president of Ramsey County Medical Society. An original skit which she wrote for the occasion was presented by Mrs. Donald Bacon. Mrs. E. A. Roberts and Mrs. Douglas Brand presented an original dialogue written around the Festival of Nations given recently at the Saint Paul Auditorium. In his talk to the gathering, Dr. H. Z. Giffin of Rochester, president of the State Medical Association, praised the work of the American Society for Control of Cancer. "Your Auxiliary," he said, "will do well to be more closely associated with this organization. When you consider that there are 50,000 deaths a year from cancer, you will realize the importance of efforts to control this disease. To carry on the work the organization must have money, and your Auxiliary has a fine opportunity for service with the Women's Field Army." In speaking of the need of confining tuberculosis carriers to sanatoria, he said, "These persons are a menace to the community when they are outside an institution. At present there is no law in respect to them. Efforts of the Minnesota Public Health Association in combating tuberculosis are to be commended."

Rice.—Mrs. Arthur W. Neutzman, Faribault, has been reelected president of the County Auxiliary.

Blue Earth.—The following are the new officers of the Auxiliary:

President—Mrs. A. F. Kemp, Mankato
 Vice President—Mrs. J. T. Schlesellman, Mankato
 Secretary—Mrs. H. Bradley Troost, Mankato
 Treasurer—Mrs. R. Wynn Karney, Mankato

Southwestern Minnesota.—Mrs. B. O. Mork, Jr. Worthington, has been reelected president of Southwestern Minnesota Medical Auxiliary.

Clay-Becker.—Mrs. C. W. Moberg, Detroit Lakes is the newly elected president of the County Auxiliary. Other officers are: Mrs. F. D. Thysell, Hawley, vice president; Mrs. S. B. Seipz, Barnesville, secretary treasurer.

Lyon-Lincoln.—Mrs. W. H. Workman, Tracy, has again been conferred the honor of president.

NO ANTERIOR ARCH

That "anterior metatarsal arch" about which foot specialists talk so learnedly just doesn't exist when the foot is at work, Dr. Herbert Eftman of the College of Physicians and Surgeons, Columbia University, told the meeting. Dr. Eftman has invented an instrument which shows the distribution of weights and pressures on the sole of the functioning foot, and it does not show the existence of an anterior arch at all. It will be necessary, therefore, he said, to re-interpret "fallen metatarsal arches" in terms of differential distribution of pressures among the ends of the metatarsals, or long bones of the foot.

Practical application of his instrument was suggested by Dr. Eftman: "The apparatus used in this investigation offers a rapid method for the accurate evaluation of the functional capacity of the feet and should be useful in determining the suitability of individuals for occupations involving sustained use of the feet."—*Science News Letter*, April 25, 1942.

REPORTS and ANNOUNCEMENTS

MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

Dr. L. A. Nelson, Saint Paul, is the new president of the Minnesota Academy of Ophthalmology and Otolaryngology. Other officers are: Dr. C. Wilbur Rucker, Rochester, first vice president; Dr. E. D. Risser, Winona, second vice president; Dr. W. A. Kennedy, Saint Paul, secretary-treasurer; Dr. George E. McGeary, Minneapolis, former secretary-treasurer, is chairman of the Council.

MINNESOTA HOSPITAL ASSOCIATION

Dr. Walter Gardner, superintendent of the Anoka State Hospital, was elected president of the Minnesota Hospital Association at the nineteenth annual convention held in Rochester, May 24, 25, and 26.

Other officers named were: Rev. L. B. Benson, superintendent of Bethesda hospital, Saint Paul, president-elect; Sister M. Assumpta, superintendent, Hibbing General hospital, first vice president; Miss Elizabeth McGregor, superintendent, Gillette State hospital, St. Paul, second vice president; and Miss Nellie Gorgas, superintendent, Saint Barnabas hospital, Minneapolis, treasurer.

J. H. Mitchell, manager Colonial hospital, Rochester, was elected delegate to the house of delegates of the American Hospital Association.

Dr. A. F. Branton, of Willmar, was reelected executive secretary, and Dr. T. E. Broadie, superintendent, Ancker hospital, Saint Paul, was reelected to the board of directors.

Presiding over the convention sessions was Miss Esther Wolfe of Minneapolis, association president.

Past presidents of the organization were presented with gold keys, this being the twenty-fifth anniversary of the Hospital Association's organization. Eleven past presidents were present to receive their keys: Dr. E. E. Mariette of Glen Lake Sanatorium, Oak Terrace; J. J. Drummond of Worrall hospital, Rochester; Paul H. Fesler of Nopeming sanatorium, Nopeming; Joseph J. Norby of Columbia hospital, Milwaukee; J. H. Mitchell of Colonial hospital, Rochester; Victor M. Anderson of Abbott hospital, Minneapolis; Dr. A. F. Branton of Willmar clinic, Willmar; Dr. Peter D. Ward, of Charles T. Miller hospital, Saint Paul; A. G. Stasel of Eitel hospital, Minneapolis, and R. M. Amberg of University hospital, Minneapolis.

G. W. Olson, administrator of Queen's Hospital in Honolulu, first president, sent greetings by radiogram.

Among medical men participating in the convention program were: Dr. Branton who presented a short history of the Minnesota Hospital Association; Dr. F. H. Krusen, Rochester, who spoke on "The War Emergency Course in Physiotherapy"; Dr. L. H. Wright of New York City, "The Anesthetist"; Dr.

Basil C. MacLean of Strong Memorial Hospital in Rochester, New York, president of the American Hospital Association; Dr. Bert Caldwell, executive secretary of the American Hospital Association, "We, The Hospitals"; Col. Wallace D. Hunt, M.D., Chief of the Medical Defense Area, Omaha; Dr. Malcolm T. MacEachern of Chicago, associate director of the American College of Surgeons who urged preparation of hospitals for any civilian defense emergency; Dr. B. F. Smith, superintendent of the State Hospital at Rochester.

Dr. Walter Judd of Minneapolis, former medical missionary in China, addressed the convention's annual banquet on "Eastern Affairs." Dr. Judd was introduced by Dr. Patrick Wu of Rochester, only Chinese to be a member of the American College of Surgeons. Dr. Charles W. Mayo introduced Dr. Wu.

Several allied groups met in conjunction with the convention.

MINNESOTA MENTAL HYGIENE SOCIETY

Rev. Edgar F. Witte of Saint Paul was elected president of the Minnesota Mental Hygiene Society, May 26, at its annual meeting in Coffman Memorial Union on the University of Minnesota campus.

Other officers named were Dr. Philip H. Heersema of Rochester, vice president; Mrs. Carl Lefevre, Minneapolis, secretary; Ralph Helstein, Minneapolis, treasurer.

Named to the directorate were Drs. R. E. Nutting, Duluth, D. E. McBroom, Saint Paul, and Starke R. Hathaway, University of Minnesota.

The executive committee will consist of the four officers together with Dr. Hathaway, Dr. H. M. Keith of Rochester, Dr. Alex Blumstein of Minneapolis, Mrs. Paul Myers of Saint Paul, Miss Anne Starks and Miss Brenda Fischer, both of Minneapolis.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The American Congress of Physical Therapy will hold its twenty-first annual scientific and clinical session September 9, 10, 11 and 12, 1942 inclusive, at the Hotel William Penn, Pittsburgh, Pa.

The annual instruction course will be held from 8:00 to 10:30 a.m., and from 1:00 to 2 p.m. during the days of September 9, 10 and 11 and will include a round-table discussion group from 9:00 to 10:30 a.m., Thursday, September 10.

The scientific and clinical sessions will be given on the remaining portions of these days and Saturday morning. A new feature will be an hour demonstration showing technique from 5:00 to 6:00 p.m. during the days of September 9, 10 and 11.

All of these sessions and the seminar will be open to the members of the regular medical profession and

"RELIEVE BACK PRESSURE"

When the back-water of the dam gets too high, the sluice-gate is opened and the lake level is dropped to a safe stage.

The arrhythmic heart is prone to produce a potentially dangerous venous congestion. DIGIFOLIN, "Ciba" by slowing down the rate, eliminating weak, ineffectual contractions, which take place before the ventricles have filled, causes a marked increase in the minute volume output of the heart, thus relieving this "back pressure."

DIGIFOLIN* can be administered orally, intravenously, intramuscularly or rectally in congestive failure, auricular fibrillation and certain other myocardial states. One tablet, one cc. of liquid or one ampule of DIGIFOLIN is equivalent to one cat unit (Hatcher and Brody method).

*Trade Mark Reg. U. S. Pat. Off.
Word "Digifalin" identifies the product as digitalis glucosides of Ciba's manufacture.

CIBA PHARMACEUTICAL PRODUCTS, INC.
Summit New Jersey

their qualified aids. For information concerning the seminar and program of the convention proper, address the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

HENNEPIN COUNTY SOCIETY

New officers of the Hennepin County Medical Society were announced at the organization's meeting, May 4, which was addressed by Dr. Leverett D. Bristol, health director of the American Telephone & Telegraph Company. His subject was "Health and Safety of War-time Workers."

The officers are: Dr. Willard David White, president; Dr. Ivar Sivertsen, first vice president; and Dr. Arthur H. McFarland, second vice president.

Dr. Thomas J. Kinsella and Dr. Ernest L. Meland were named to the executive committee; Dr. McFarland and Dr. Charles N. Spratt, board of censors; Dr. Russell W. Morse and Dr. Otto W. Yoerg, board of trustees; and Dr. Axel E. Hedback and Dr. Kinsella, ethics committee.

Named as delegates to the Minnesota State Medical Association were Drs. Chauncey A. McKinlay, Kenneth H. Phelps, Ray R. Knight, Lawrence F. Richdorf, and Thurston W. Weum. Alternates are: Drs. William H. Aurand, Adam M. Smith, Joseph C. Michael, Frank R. Hirshfield and Moses Barron.

MINNEAPOLIS SURGICAL SOCIETY

Officers of the Minneapolis Surgical Society for 1942-43 are: Dr. Richard R. Cranmer, president; Dr. H. O. McPheeters, vice president; and Dr. Robert F. McGandy, secretary-treasurer.

Members of the Executive Council include, besides the officers: Dr. Arthur Bratrud, retiring president; and Drs. R. C. Webb, Henry M. Lee, S. R. Maxeiner, William A. Hanson and Otto Yoerg.

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held its regular monthly meeting May 12, 6:30 p.m., at the White Pine Inn, Bayport, Minnesota.

The guest speaker, Merritt W. Wheeler, M.D., of Saint Paul, told of the "Anatomy, Pathology, Surgical Steps and Reasons Therefore", as his colored movies of external sinus operations were being run; he cited cases and results and answered numerous questions, which were all very interesting and instructive.

The Washington County Medical Society has now completed the vaccination against smallpox and diphtheria immunization in all the schools in the county. The enthusiastic coöperation of Mr. Guy D. Smith for the city schools in Stillwater and Mrs. Grace McAlpine, County Superintendent of Schools and the willing enthusiastic help of all the teachers made this possible.

The county's Health Relations Committee is now planning for further closer coöperation with the Parent-Teacher Association.

OF GENERAL INTEREST

Dr. F. H. Rollins of St. Charles was reelected to the St. Charles board of education last month.

* * *

A son was born to Dr. and Mrs. Burtrum C. Schiele of Minneapolis, April 21.

* * *

Dr. and Mrs. R. D. Davis of Clearbrook announce the birth of a son, April 24.

* * *

Twins, a son and a daughter, were born to Dr. and Mrs. Cyrus O. Hansen of Minneapolis, May 7.

* * *

Dr. and Mrs. Charles E. McLennan of Minneapolis are the parents of a daughter, Nancy Ann, born May 3.

* * *

Born to Dr. and Mrs. Carl O. Rice of Minneapolis, a daughter, Sara-Jae Gronna, March 28.

* * *

A daughter was born to Dr. and Mrs. Leonard A. Lang of Minneapolis, May 12.

* * *

Dr. and Mrs. D. Kalinoff of Stillwater returned in April from a visit in the South. Their daughter, Helen, was operated upon for appendicitis on May 8.

* * *

Dr. William F. Braasch of Rochester is state chairman of the Procurement and Assignment Service, medical doctors section.

* * *

Dr. William Gjerde of Staples was recently promoted to the rank of captain, Medical Corps, at the Aviation School at Randolph Field, Texas.

* * *

Dr. Nathan J. Berkwitz of Minneapolis was in Boston, May 19, to present a paper before a meeting of the American Psychiatric Association.

* * *

Among those recently certified by the American Board of Surgery are Drs. Donald C. MacKinnon, Hamlin A. N. Mattson, and Louis Sperling of Minneapolis.

* * *

Dr. R. B. Potter has taken over the practice of the late Dr. W. W. Moir in the Nicollet and Lake Medical Building, Minneapolis. He has been in this location since Dr. Moir's death in February.

* * *

Dr. James Doyle Ryan of Fairfax became associated in practice with Dr. C. J. Henry in Milaca, May 15. A graduate of the Saint Louis University, he interned at Saint Luke's hospital in Minneapolis.

* * *

Married May 10 in Saint Paul were Miss Bernis Nides of Hibbing and Dr. Victor J. Birnberg. Dr. Birnberg is the son of Dr. and Mrs. Ansel N. Birnberg of Saint Paul and White Bear Lake. The couple will make their home in Saint Paul.

Dr. Ruth E. Boynton, director of the Students' Health Service at the University of Minnesota, was elected a member of the board of directors of the Minnesota League of Women Voters at the recent annual meeting.

* * *

Dr. Owen H. Wangenstein of Minneapolis, head of the department of surgery at the University of Minnesota Medical School, addressed the Chicago Surgical Society, May 1, on the subject "The Surgical Aspects of Peptic Ulcer."

* * *

From the Chinese Army on the eastern front in Burma comes news of a Minnesota doctor, Captain Donald M. O'Hara of Janesville. Captain O'Hara is working with the fabulous surgeon-missionary, Dr. Gordon S. Seagrave.

* * *

Dr. Joseph Berkson of Rochester has been assigned to the office of the air surgeon of the United States Army air forces in Washington, D. C. He will be in charge of medical statistics in the air surgeon's office and will have the rank of major.

* * *

Dr. Wesley W. Spink, associate professor of medicine at the University of Minnesota Medical School, was elected secretary of the American Society for Clinical Investigation at its meeting in Atlantic City last month.

* * *

Minneapolis doctors who have entered the military service include Dr. Vernon L. Hart and Dr. Delph T. Stromgren. Dr. John H. Moe will continue the practice of Dr. Hart, and Drs. H. P. Linner and E. H. Dunlap will continue for Dr. Stromgren.

* * *

Dr. Arnold Settlege, former staff member of the Worthington Clinic in Worthington, is now attached to the recruit reception center at Fort Devens, Massachusetts. He is a first lieutenant in the Army Medical Corps.

* * *

Among papers presented at the thirty-fourth annual meeting of the American Society for Clinical Investigation in Atlantic City, May 4, was one on "The Effect of Promin on the Blood of Tuberculosis Patients" by Drs. Byron E. Hall, Horton C. Hinshaw of Rochester and Dr. Karl H. Pfuetze of Cannon Falls.

* * *

Dr. William T. Peyton, director of the division of neurosurgery at the University of Minnesota Medical School, presented a paper, "The Relief of Intractable Pain," at the annual meeting of the Nebraska State Medical Association in Omaha, May 4-5.

Also on the program was Dr. Henry W. Woltman of Rochester. His paper was entitled "Postoperative Neurologic Complications."

Dr. Harold I. Lillie of Rochester was named first vice president of the American Laryngological Association at its meeting in Atlantic City, New Jersey, last month. Dr. Charles J. Imperatori of New York was elected president.

* * *

Among speakers at the forty-eighth annual session of the American Laryngological, Rhinological and Otolological Society, held in Atlantic City, New Jersey, June 1-3, was Dr. Gordon B. New of Rochester. His subject was "The Treatment of Congenital Cysts of the Larynx."

* * *

Dr. William E. Proffitt, Jr., of Minneapolis, former University of Minnesota halfback, reported for duty with the Army Medical Corps at San Luis Obispo, California, May 11. He is a first lieutenant. Dr. Proffitt starred on the 1934 national championship football team.

* * *

Dr. Donald Duncan, a graduate of the University of Minnesota Medical School, has been appointed professor and head of the department of anatomy at the University of Buffalo Medical School in Buffalo, New York. Dr. Duncan, who has been with the University of Texas, formerly taught in the medical schools of Minnesota, Buffalo and Utah universities.

* * *

At the ninth annual meeting of the American Rheumatism Association to be held in Atlantic City, New Jersey, June 8, a paper, "An Analysis of the Manner of Death Among Thirty Patients with Rheumatoid Arthritis," was presented by Drs. Edward F. Rosenberg, Archie H. Baggenstoss and Philip S. Hench of Rochester.

* * *

Among new Fellows in the Mayo Foundation at Rochester is Dr. John A. Tweedy of Winona. A graduate of the University of Minnesota Medical School, he interned at the Charles T. Miller hospital in Saint Paul 1936-37. Since December 1937, he has been in practice and on the staff of the Winona General Hospital.

* * *

Dr. A. G. Liedloff of Mankato was reelected chairman of the executive board of the Blue Earth County Public Health Association at its annual meeting, May 14. Dr. William A. O'Brien, director of postgraduate medical education at the University of Minnesota, was principal speaker. His subject was "Recent Advances in Public Health."

* * *

The Minnesota Human Serum Laboratory has been called to active duty by the Minnesota State Guard, and will be known as the First Medical Detachment of the Minnesota State Guard.

Its function will be to prepare a reserve of human serum to be used by military and civilian organizations in the state in case of bombing or sabotage.

Dr. Paul F. Dwan of Minneapolis is commanding officer with the rank of major.

Herald R. Cox, ScD., associate bacteriologist with the United States Public Health Service, stationed at the laboratory in Hamilton, Montana, delivered the second annual *Journal-Lancet* lecture at the University of Minnesota Medical School, Minneapolis, May 22. His subject was "Typhus Fever, with Special Reference to Epidemiology and Immunity."

* * *

Regulations for the administration of the Blood and Plasma Bank Program of the Medical Division of the United States Office of Civilian Defense have now been prescribed, and funds are available for grants to assist approved hospitals in establishing blood and plasma banks. Only hospitals within 300 miles of the Atlantic, Pacific or Gulf coasts are eligible for such grants.

* * *

A grant of \$30,000 from the W. D. Kellogg Foundation at Battle Creek, Michigan, has been accepted by President Walter C. Coffey of the University of Minnesota, for the use of students in medicine, dentistry and public health. The money will be used to aid students who usually earn their tuition by working summers. Because of the accelerated program which eliminates summer vacations, this is no longer possible.

* * *

Dr. Edgar W. Bedford of Minneapolis moved his offices last month into his newly constructed clinic building at 2862 Hennepin Avenue.

The one-story building, which will also house offices of two dentists, has a full basement, most of which is given over to laboratories. Reception and consultation rooms on the main floor are paneled with Philippine mahogany. A large parking place is provided for at the rear of the building.

* * *

Presiding at the thirty-second annual meeting of the medical section, American Life Insurance convention held in Colorado Springs, Colorado, June 4-6, was Dr. Thomas N. Dickson of Saint Paul, medical director of the Minnesota Mutual Life Insurance Company.

Dr. Dickson was elected vice chairman of the medical section last June and became chairman in April following the death of Dr. W. F. Blackford of Louisville, Kentucky.

* * *

Dr. William A. O'Brien, professor of preventive medicine and public health and director of postgraduate medical education at the University of Minnesota, delivered the commencement address at high school graduation exercises in New London, May 27, and at Hendricks, May 28.

He also was commencement speaker at the exercises of St. Mary's School of Nursing in Minneapolis, May 10.

* * *

Appointment of Dr. Albert G. Schulze, Saint Paul physician, as a member of the Ramsey County Welfare Board, is announced by Mayor John McDonough. The appointment is for the unexpired term of the late Dr. C. F. McNevin, which ends July 1, 1943.

Dr. Schulze has served as president and secretary

BIOLAC is complete and replete...

...because there is no lack in Biolac, except for vitamin C. Biolac feedings provide amply for all other nutritional requirements of the normal young infant, and no additional formula ingredients or supplements are necessary. It's an improved evaporated-type infant food with breast-like nutritional and digestional advantages. It is a complete formula, replete with nutritional values. Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrates of vitamins A and D from cod liver oil, and ferric citrate.

Prescribe Biolac in your next feeding case. Professional literature on request. Write Borden's Prescription Products Division, 350 Madison Ave., New York, N. Y.

Why BIOLAC is increasingly popular:

- Ample provision for high protein needs of early months
- Reduced fat for greater ease in digestion
- Enriched with vitamins A, B₁, D and iron
- All needed carbohydrate present as Lactose
- Sterilized for formula safety
- Homogenized to improve digestibility
- Easy to prescribe
- Convenient for mothers to use
- Economical: because it's complete

Borden's BIOLAC

A BORDEN PRESCRIPTION PRODUCT

of the Ramsey County Medical Society, and is a member of the Minnesota State Board of Health. He heads the obstetrics and gynecology department of Ancker Hospital.

* * *

When the North Dakota State Medical Association held its annual meeting in Jamestown, May 18-20, the program included papers by Dr. Erling S. Platou, Minneapolis, "Pediatrics"; Dr. Stanley R. Maxeiner, Minneapolis, "Fractures"; Dr. Lawrence R. Boies, Minneapolis, "Symptom of Headache"; and Dr. Gordon R. Kamman, Saint Paul, "The Depressed Patient."

Dr. Edward C. Rosenow of Rochester participated in a symposium on "Infectious Encephalomyelitis."

* * *

Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota, has been named chairman of the newly organized Committee on Allocation of Medical Personnel under the Procurement and Assignment Service for Physicians, Dentists and Veterinarians of which he is a member of the board.

Dr. Diehl attended a meeting of the new committee in Washington, D. C., May 17, and a meeting of the directors' board of the Procurement and Assignment Service, May 18.

* * *

The University of Minnesota Medical School has instituted two new courses for senior medical students in anticipation of their entering military service following completion of their internships.

The courses are: War Medicine, which will consist of a series of lectures by specialists in the field, to be given from 8 to 9 a.m., Mondays, Wednesdays and Fridays during the summer session; and Tropical Medicine, which will be given during the fall and winter quarters, Mondays and Wednesdays from 3 to 4 p.m.

* * *

Dr. John L. Rothrock of Saint Paul recently received the highest honor conferred by Gettysburg College at Gettysburg, Pennsylvania, on its alumni at a ceremony there. He was presented the Alumni Meritorious Service award.

Graduated from the college in 1885, Dr. Rothrock practiced medicine in Saint Paul from 1890 until 1936 when he retired. He was on the staff of the University of Minnesota Medical School from 1895 to 1936, when he was made professor emeritus of obstetrics and gynecology.

* * *

Dr. Henry F. Helmholtz of Rochester was awarded the Minnesota Public Health Association's Christmas Seal distinguished service plaque, May 22, in connection with the ceremony honoring Olmsted County for its tuberculosis record. The plaque was presented him for his public health and Christmas Seal work in Olmsted County over the past twenty years.

Only two other Minnesotans have previously been given the award, presentation of which was made by Dr. E. A. Meyerding, executive secretary of the Minnesota Public Health Association.

Courses for physicians in the Kenny technique for the management of acute phase of poliomyelitis, will be given at the University of Minnesota Center for Continuation Study June 1-6, July 6-11 and August 10-15.

Courses for nurses in the application of hot fomentations will also be given at the Center, June 15-20 and July 13-18. The first of this series for nurses was held May 25-29.

In addition to these courses, technicians are being trained in periods of two to six months' duration.

Dr. Miland E. Knapp is Director of Training Courses in Kenny Technique.

* * *

Dr. George E. Holm, biochemist with the bureau of dairy industry, United States Department of Agriculture, Washington, since 1920, has been awarded the Borden Company prize of \$1,000 in recognition of "his contributions to the understanding of the basic causes and the control of oxidative deterioration of fats and oils, and to the prevention of spoilage of dairy products caused by the oxidation of milk fat." The prize is awarded through the American Chemical Society for "outstanding research in the chemistry of milk."

Dr. Holm received his Ph.D. from the University of Minnesota in 1919.

* * *

Minneapolis physicians who have reported for duty with the United States Navy include Dr. Kenneth E. Fritzell and Dr. Philip A. Arling who have joined the Minneapolis delegation at Great Lakes Naval Training Station.

Dr. William P. Sadler, lieutenant commander, has reported for duty at the Norfolk Navy Yard. His entering the service made it impossible for him to accept an invitation to deliver the commencement address at the Van Buren (Arkansas) High School. Dr. Sadler rates with Bob Burns as one of the most distinguished sons of that school.

* * *

To break the "bottleneck" of procuring birth certificates for defense work, the Minnesota Board of Health has assigned Dr. D. A. Dukelow of Minneapolis, director of Public Health Education, to take active charge of the division of vital statistics.

Appointment of Dr. Dukelow was made upon recommendation of a board of health committee, composed of Dr. Ruth E. Boynton and Professor F. E. Bass of the University of Minnesota.

More than 7,500 applications for birth certificates have piled up as a result of persons either enlisting in the military services or applying for employment in war industries, where proof of citizenship is required.

* * *

Among those who addressed the special course in obstetrics given at the University of Minnesota Center for Continuation Study, May 11-16, were Dr. John H. Moore of Grand Forks, North Dakota, president of the Central Association of Obstetrics and Gynecology, and Dr. Ralph A. Reis, assistant professor of obstetrics

and gynecology at the Northwestern University Medical School.

The course was attended by a group of physicians from North Dakota and South Dakota, sent by their state health departments. In attendance the last three days were a group of Minnesota physicians, sent by the State Department of Health.

* * *

So that adequate medical aid will be available in case of any war emergency, ranging from an air raid to an industrial accident in a war plant, Saint Paul has set up a Medical Civilian Defense Committee, headed by Dr. Robert Schoch, city health officer.

This committee is directing the coördination of the work of civil authorities, hospitals, medical and nursing groups, and is preparing for hospital field units, casualty stations and decontamination stations. A complete emergency field unit has already been set up at four hospitals; twenty-three district casualty stations have been designated; and fifty buildings have been made available as decontamination stations where victims of gas attacks could be treated.

* * *

An honorary degree of LL.D. was conferred upon Dr. O. J. Hagen of Moorhead at the Fiftieth Anniversary Commencement of Concordia College, Moorhead, June 2.

Dr. Hagen was a former instructor at the college, and for ten years a member of its Board of Trustees. Among the various positions of responsibility Dr. Hagen has held are: president of the Minnesota Public Health Association, member of the Minnesota State Board of Health, member of the Board of Regents of the University of Minnesota. In 1936, he was elected to the presidency of the National Governing Board of State Universities and Allied Institutions, and in 1941 was made a fellow of the International College of Surgeons at Mexico City.

* * *

Dr. and Mrs. Joseph B. Friberg, formerly of Saint Paul, are on their way to Tanganyika Territory in the interior of Africa where they will serve as medical missionaries to 300,000 natives. They will be stationed at the town of Iambi. Their service in Africa will be under the auspices of the Board of Foreign Missions of the Augustana Lutheran synod which has headquarters in Minneapolis.

Born in China, son of missionary parents, Dr. Friberg was graduated from the University of Minnesota Medical School. He served his internship at Miller Hospital and practiced medicine in Saint Paul before accepting his new appointment. Mrs. Friberg is a graduate of the University of Minnesota School of Nursing.

* * *

Captain John H. Grindlay of Rochester, former Mayo Foundation fellow, was one of the group of twenty-six foot-weary American physicians, civilians and military men who marched out of Burma into India with Lieutenant General Joseph H. Stilwell.

An Associated Press dispatch from New Delhi dis-

"EUREKA, I BELIEVE THIS IS IT!" Said A Doctor When He Saw This New Spencer Brassiere

A physician, after seeing a demonstration of the new Spencer Uplift Brassiere on one of his patients, exclaimed, "Eureka, I believe this is it!" He had been seeking a Brassiere that would adequately support heavy breasts, without compression.

This new Spencer Brassiere is *individually designed*, cut and made for the one patient who is to wear it. It supports and holds the breasts in natural position, thus improving the circulation of the blood through the breasts.

When worn during pregnancy, this new Brassiere helps prevent outer skin from stretching and breaking. During the nursing period, it helps prevent caking.

Special Sleeping Brassieres Augment Day-Time Treatment

This new Brassiere may also be designed for wear during sleeping hours, so that your prescribed treatment will be constant. It is designed to permit automatic adjustment to the turning and twisting of the body during sleep, yet provides positive uplift for the breasts.

For service at your office, the hospital or patient's home, look in telephone book under "Spencer Corsetiere" or write direct to us.

MAY WE SEND YOU THIS BOOKLET?

Address.....

Pentobarbital Sodium (Gane), manufactured by Gane's Chemical Works for the pharmaceutical industry, is available to the medical profession through many pharmaceutical houses at prices which compare more than favorably with those of other sedative and hypnotic drugs.

Pentobarbital Sodium has justly gained wide professional acceptance, not merely because it is probably the most widely investigated barbiturate, but mainly because it offers these advantageous properties:

It is effective in small dosage, yet there is a relatively wide margin of safety between therapeutic dosage and the minimum lethal dose. * * * Induction of sleep is prompt, yet gradual. Within 30 minutes after administration the patient becomes drowsy, and sleep sets in. * * * Since Pentobarbital Sodium is destroyed in the body with comparative rapidity, the induced sleep is of relatively brief duration, six to eight hours. * * * With proper regulation of dosage there is rarely any post-sleep depression—the patient usually wakes refreshed, clearheaded, as from normal sleep of similar duration.

Pentobarbital Sodium finds many uses—in sleeplessness or insomnia; for preanesthetic sedation in surgery; for amnesia and analgesia in obstetrics; in hyperemesis gravidarum; in eclampsia, neurasthenia, neuroses, hysteria, delirium tremens. In conjunction with analgesics and narcotics, whose action it enhances, it is of value in combating the pain of neuralgia.

GANE'S CHEMICAL WORKS, Inc.

Manufacturing Chemists

43 WEST 16TH STREET NEW YORK, N.Y.

closed that the former Rochester physician was among the Americans who journeyed 104 miles legging it through jungles, across steaming rivers and among head-hunting Burmese to reach India. Most of the time they were just a couple of jumps ahead of the Japanese.

Leaving Rochester in November, 1940, Captain Grindlay went to the Walter Reed General Hospital Army Medical Center at Washington.

* * *

In a move to cut red tape and to commission additional medical officers as rapidly as possible, the Army last month opened an office in Saint Paul to recruit doctors and dentists from Minnesota. The office is at 496 Lowry Medical Arts Building, adjoining offices of the Minnesota State Medical Association and the State Dental Association.

In charge are Major C. A. Wood of Fort Leavenworth, Kansas, and Major Baptiste Groebner of Fort Snelling.

Through regulations unique in Army procedure, the two officers are empowered to put through commissions in three or four days, as compared with the usual average of three months. They will make final decisions on the spot and administer oaths of service.

Men accepted will be given time to wind up their affairs before reporting for duty.

The office will be the only one of its type in Minnesota.

About 500 Minnesota physicians have been classed as "available" for military service by committees functioning under the Procurement and Assignment Service, according to Col. J. E. Nelson, state selective service director.

* * *

Endowed with the income of a fund of more than \$100,000 left to the University of Minnesota by the late Dr. Charles F. Dight of Minneapolis, the Charles Fremont Dight Institute for the Promotion of Human Genetics is now in operation on the University of Minnesota campus.

Dr. Clarence P. Oliver is its director. Among members of the institute committee is Dr. Eric Kent Clarke director of the Psychiatric Clinic for Children.

Studies within the field of genetics and eugenics will be directed particularly at present to "a search for traits, such as metabolic disturbances, which may have genetic bases, but are not recognized as hereditary traits."

Family data and records bearing on the inheritance of defects would be greatly appreciated by the Institute. Among family records particularly desired are those on nervous disorders, blindness, dental defects, blood diseases, twins and long-lived families.

First lecture under the auspices of the Institute was

delivered April 10 when Dr. Philip Levine of the Newark Beth Israel Hospital in Newark, New Jersey, discussed "Serological Differentiations of Human Blood."

* * *

An In-Service Health Training Program for teachers of rural schools in Saint Louis County was concluded last month. It consisted of five sessions. Speakers included several physicians.

At the first meeting Dr. E. L. Tuohy of Duluth, chairman of Public Health Education, Minnesota State Medical Association, spoke on "General Orientation"; Drs. Charles B. Cunningham and Walter S. Neff, both of Virginia, and Drs. Selma Mueller and W. E. Hatch of Duluth, spoke on "The Teacher's Health."

Dr. Viktor O. Wilson of Minneapolis, director of the Division of Child Hygiene, Minnesota State Department of Health, spoke on "Educational Aspects of School Health Services" at the second session; while Dr. Donald A. Dukelow of Minneapolis, director of public health education, State Department of Health, discussed "Health Education."

Included on the program for the third session were Dr. C. A. Scherer, county health officer of Saint Louis County, who had for his topic, "Environmental Health" and Dr. A. T. Laird, superintendent of Nopeming Sanatorium, Nopeming, who spoke on "Tuberculosis."

At the fourth session, Dr. Mario Fischer, director of public health, Duluth, discussed "A Communicable Disease Control Program."

The final session, a dinner meeting, was held May 1. Dr. C. M. Jessico of Duluth, spoke on "Mental Hygiene" and Dr. W. A. O'Brien, director of postgraduate medical education at the University of Minnesota, presented a summary.

* * *

A large number of Minnesota physicians will participate in the ninety-third annual session of the American Medical Association in Atlantic City, June 8-12.

Minnesota members of the House of Delegates are: Drs. A. W. Adson of Rochester, James M. Hayes of

ANNOUNCES CONTINUOUS COURSES

SURGERY—Two Weeks Intensive Course In Surgical Technique with practice on living tissue, every two weeks throughout the year. General Courses One, Two, Three and Six Months; Clinical Courses; Special Courses.

MEDICINE—Two Weeks Intensive Course will be offered starting October 5. Two Weeks Course in Gastro-Enterology will be offered starting October 19. Two Weeks Intensive Course in Electrocardiography and Heart Disease starting August 3.

FRACTURES & TRAUMATIC SURGERY—Two Weeks Intensive Course will be offered starting June 29 and September 21. Informal Course available every week.

GYNECOLOGY—Two Weeks Intensive Course will be offered starting October 5. One Month Personal Course starting August 3. Clinical and Diagnostic Courses every week.

OBSTETRICS—Two Weeks Intensive Course will be offered starting September 21. Three Weeks Course starting August 10. Informal Course every week.

OTOLARYNGOLOGY—Two Weeks Intensive Course will be offered starting September 14. Clinical and Special Courses every week.

OPHTHALMOLOGY—Two Weeks Intensive Course will be offered starting September 28. Five Weeks Course in Refraction Methods starting October 19. Informal Course every week.

*General, Intensive and Special Courses in All Branches
of Medicine, Surgery and the Specialties.*

**TEACHING FACULTY — ATTENDING
STAFF OF COOK COUNTY HOSPITAL**

Address: Registrar, 427 S. Honore St., Chicago, Ill.

Minneapolis, W. A. Coventry of Duluth and Francis J. Savage of Saint Paul.

Dr. Louis A. Buie of Rochester is a delegate from the Section of Gastro-enterology and Proctology.

Among the speakers at the General Scientific meetings will be Dr. Wallace H. Cole of Saint Paul, who will present a paper on June 9, "An Evaluation of the Kenny Treatment of Poliomyelitis."

Dr. Fred W. Rankin of Lexington, Kentucky, formerly of Rochester, will be installed as president at the opening general meeting, June 9.

Minnesota people, who will take part in the programs of the various sections, follow:

Section on Practice of Medicine (Joint meeting with Section on Experimental Medicine and Therapeutics of which Dr. Edgar V. Allen, Rochester, is section secretary): Paper, "Dicoumarin [3,3'-Methylene-Bis-(4-Hydroxycoumarin)]"—Experimental Studies by Drs. Jesse L. Bollman and F. W. Preston of Rochester; Clinical Studies by Drs. Edgar V. Allen, Nelson W. Barker and John M. Waugh of Rochester. Paper, "An Analysis of the Operative Treatment of Patent Ductus Arteriosus," by Drs. M. J. Shapiro and Ancel B. Keys of Minneapolis.
